the action of the trioxide itself upon moisture. Sulphur trioxide has a powerful affinity for water, in which it dissolves with a hissing noise and the formation of sulphuric acid, as indicated by the equation $\text{H}_2\text{O} + \text{SO}_3 \rightarrow \text{H}_2\text{SO}_4$. The reaction is accompanied by the liberation of a great deal of heat.

Sulphur combines directly with carbon, at a red-heat, with the formation of a substance known as carbon disulphide ($\text{C}_8\text{S}_2$) or (carbon bisulphide), which has the chemical formula CS$_2$. This action of which that is this produced may be condensed to a very volatile, mobile liquid, possessing a high dispersive action upon light. Carbon disulphide freezes at about $-166$° F., boils (under a pressure of one atmosphere) at $115$° F., has a specific gravity of 1.29 and a specific heat of 0.247, and is used as a solvent for resins, sulphur, phosphorus, gutta percha and many other substances that do not dissolve in water. It is almost insoluble in water, but mixes readily with alcohol, ether and many kinds of oil. It is exceedingly inflammable, and its vapor forms explosive mixtures with air. The vapor of carbon disulphide takes fire when heated in contact with air to 300° F., and this circumstance, taken in connection with the volatility of it is substance and the explosiveness of its vapor when mixed with air, renders the use of the disulphide exceedingly dangerous in the presence of any sort of a flame, or even in the presence of bodies heated as hot as 300° F. As ordinarily met with in commerce, carbon disulphide possesses an exceedingly efficacious odor; but this is due to impurities, and when these are removed, the pure disulphide has an ethereal odor, which is not objectionable. The vapor of carbon disulphide is poisonous, even when greatly diluted with air.

The known compounds that contain sulphur in combination with two or more other elements are almost innumerable, as are also the uses to which sulphur is put in the arts. Among the sulphur compounds containing sulphur with two or more other elements, the various salts of sulphurous and sulphuric acids are exceedingly important. For data concerning sulphur black and the sulphur compounds that are in general use in the coal color industry, consult Chas. T. Thompson, "The Synthetic Dyestuffs and Intermediate Products"; also Wahl and Atack, "The Manufacture of Organic Dyestuffs."

ALLAN D. RISTEN.

SULPHUR, Medical Uses of. Sulphur is prepared in various ways for use, both internally and externally, in medicine. It is used in the forms of washed, precipitated or milk of sulphur, and sublimate powders, or flowers of sulphur, corresponding to the manner of its preparation from crude sulphur — by washing, precipitation, or sublimation. The precipitated sulphur is regarded as the most efficacious, perhaps because of its finer division, which is chemical instead of mechanical. It is prepared by boiling equal parts of sulphur and freshly slacked lime for an hour, and then adding dilute hydrochloric acid until the alkali almost disappears. The sulphur precipitates as a white powdery mass, and is washed and dried at a low temperature. Precipitated sulphur is much employed as a mild laxative, taken in medicinal doses and by its action facilitates evacuation in cases where intestinal or rectal disorders pain-

fully interfere. Sulphur is also a valuable remedy in certain blood-diseases, chronic skin-diseases, chronic bronchitis, chronic rheumatism, etc., both internal administration — especially in the form of mineral waters containing sulphur — and sulphur baths being often efficacious. The administration of sulphur in obstinate chronic cases of many diseases often works such a change in the patient's condition as to give potency to other remedies given without effect. As a parasiticide, and especially in skin affections, ring-worm, itch, etc., sulphur ointment is a specific, or at least an active curative agent.

SULPHUR DIOXIDE. See Liquefied and Compressed Gases.

SULPHUR DYESTUFFS. See Coal Tar Colors.

SULPHUR SPRINGS, Tex., city, county-seat of Hopkins County, on the Missouri, Kansas and Texas, and the Saint Louis Southwestern railroads, about 240 miles northeast of Austin, the capital, and 75 miles northeast of Dallas. It is in an agricultural and stock-raising region and has an extensive domestic export trade in cotton products, wheat, corn, fruit (peaches and plums), honey, poultry and livestock. It has two national banks, a combined capital of $200,000. The educational institutions are the Central College (Methodist Episcopal, South), opened in 1876, and public schools. Pop. about 5,151.

SULPHURETTED HYDROGEN (H₂S), a gaseous compound of hydrogen and sulphur, found abundantly in nature in gases issuing from crevices in volcanic regions, and occasionally in natural gas. It is one of the common products of decomposition of vegetable substances, especially those of the lecanum family. It occurs in illuminating gas, from which it is scrupulously removed at considerable expense. It is prepared on a large scale by heating together equal parts of vaseline or paraffin and sulphur.

Sulphuretted hydrogen is a colorless, inflammable gas, burning with a bluish flame, and having an extremely offensive odor, similar to that of rotten eggs. It is very poisonous; when inhaled in small quantity producing nausea and headache, and in large quantity, asphyxiation. One part of the gas in 200 parts of air is fatal to horses, and one part of gas to 300 of air is fatal to dogs. It is soluble in water in the proportion of 4.4 volumes of gas to 1 volume of water at 32° F. At higher temperatures less of the gas is held in solution. Alcohol at 32° dissolves 17.9 times its own volume.

The aqueous solution of sulphuretted hydrogen is known as hydro sulfurous acid. It smells of the gas, and decomposes on standing, depositing sulphur, and the hydrogen oxidizing into water. Its solution in glyzerine, however, keeps good for a long time.

The gas may be liquefied at ordinary temperatures by submitting it to a pressure of 17 atmospheres — that is, about 250 pounds to the square inch. Liquid sulphuretted hydrogen is a colorless, volatile liquid which freezes or solidifies at $-117$° F, and boils at $-79$°. In its liquid form it is nearly inert chemically.

Sulphuretted hydrogen is used in large
quantities in the manufacture of sulphuric acid to remove the arsenic which is found in larger or smaller percentage in all acid made from pyrites. It is also used to precipitate copper from solutions containing salts of copper, and for precipitating gold and silver from sweepings and other waste material. In the chemist’s laboratory it is one of the most valuable reagents.

SULPHURIC ACID, or OIL OF VITRIOL, a common and exceedingly important oxy-acid of sulphur, having the chemical formula H₂SO₄. It was first prepared by Geber, in the 8th century, by distilling alun; and in the 15th century it was manufactured by burning sulphur with saltpetre, though the identity of the product so obtained with that described by Geber was not established until near the end of the 16th century. Considerable quantities of sulphuric acid were formerly manufactured by the distillation of ferrous sulphate, the practice of this method dating from the early part of the 18th century. At the present time practically all of the sulphuric acid that is prepared is from sulphur dioxide gas, either by the “chamber process,” or by the more recently perfected contact process, both of which are described in this article.

When pure and free from water, sulphuric acid is a colorless liquid with an oily appearance, and a specific gravity of 1.89. It may be readily frozen, the solidified acid melting again at 30° F. It exhibits the phenomenon of sublimation to a marked extent, and the liquid acid can be cooled, much below the melting point here given, without inducing solidification; but if a crystal of the solid acid, or a small amount of sulphur trioxide, be added to the supercooled fluid, crystallization begins at once, and the temperature rises until it becomes 50° F, after which no further solidification occurs. The presence of a trace of water in the acid lowers the freezing point nearly to 32° F. If five parts (by weight) of sulphuric acid be mixed with nearly one part of water, and the solution is cooled by a freezing mixture, a definite hydrate of sulphuric acid, having the composition H₂SO₄·H₂O, crystallizes out at 45° F. A solid hydrate, having the composition H₂SO₄·4H₂O, may also be prepared by cooling, to a much lower temperature, a mixture of sulphuric acid and water, containing 57.6 per cent of water. Several other hydrates are also believed to exist, and special study has been expended upon them, on account of their importance in the illustration of the hydrate theory of solutions. (Consult Mendeleeff, Principles of Chemistry, Vol. II.) Sulphuric acid has no really definite boiling point. It begins to boil at about 550° F, the distillate containing sulphuric acid, water and sulphur trioxide. (See SULPHUR.) The temperature of the liquid may be raised to 640° F, however, without danger. This definition is not so much in conformity to the boiling point of water, the vapor that passes off then consisting entirely of water vapor and free sulphur trioxide. At higher temperatures the decomposition is even more complete. Thus if a stream of the acid is allowed to flow over red-hot not being broken up into sulphur dioxide (SO₂), free oxygen and water-vapor. If the gases resulting from this decomposition are passed through cool water, and the steam that they contain is condensed and the sulphur dioxide removed by solution, a supply of pure oxygen gas is obtained. Pure anhydrous sulphuric acid has a specific heat, at ordinary temperature, of about 0.34, and a coefficient of expansion (Fahrenheit scale) of about 0.000310. The concentrated acid is a powerfully corrosive poison, destroying organic tissues rapidly, and even charring paper and wood. It is also poisonous (though far less violently so) when administered in any considerable quantity in a highly dilute form. Concentrated sulphuric acid has a powerful affinity for water, its combination with water being attended by the evolution of a large amount of heat. The strong acid is used as a drying agent, for removing moisture from gases. For this purpose it is sometimes sufficient to allow the gas to stand for a time in a receiver containing a dish of the concentrated acid; but a more effective result may be obtained by passing the gas through tubes that are partially filled with fragments of pumice that have been wetted with the acid.

Chemically, sulphuric acid is dibasic, either or both of its hydrogen atoms being replaceable by metals or other bases, the compounds that are thus formed being termed sulphates. With the metals of the alcali (which are monovalent), sulphuric acid therefore forms two kinds of compounds, which may be sufficiently illustrated by the potassium salts. If one of the hydrogen atoms of the acid is replaced by potassium, the resulting salt, HKSO₄, is called potassium sulphate; or acid potassium sulphate; while if both are replaced, the resulting salt has the formula KH₂SO₄, and is known as potassium sulphate. Many of the sulphates of the metals occur native in large quantities, and many of them are of great value in the arts. Those that are of especial importance are described, in this encyclopedia, under the metals (or other bases) with which the acid is combined. The sulphate of barium is perhaps the most insoluble salt known. It is formed whenever a soluble barium salt (such as the chlorate) is added to a solution of a soluble sulphate, and this formation constitutes a valuable test for sulphuric acid and the sulphates. See Chemical Analysis.

When sulphur trioxide is dissolved in anhydrous sulphuric acid in the proportion of one molecule of the trioxide to one of the acid, a definite compound having the formula H₅SO₃O (or H₅SO₃O₄) is obtained. When pure, this substance is known as pyrosulphuric acid. It is a dibasic acid, forming salts which are termed pyrosulphates. Pyrosulphuric acid (now commonly known in the arts as oleum) but formerly called “Nordhausen oil of vitriol” consists of a mixture of pyrosulphuric acid and ordinary sulphuric acid and may be regarded as a solution of sulphur trioxide in sulphuric acid. Pyrosulphuric acid is broken up into a quantity to convert the ordinary acid entirely into pyrosulphuric acid. It fumes strongly in the air, gives off sulphur trioxide when heated,
and is prepared by the "contact process," described in this article.

The uses of sulphuric acid in chemistry and in the arts are past enumeration; for this acid is one of the most important chemical substances known, and it is employed in so many industrial processes that it has been said that the wealth and prosperity of a nation can be estimated from its consumption of sulphuric acid. About half of the total quantity manufactured in the United States is consumed in the preparation of fertilizers. The two general methods now in use for manufacturing the acid are described in this article.

The sulphur used for the manufacture of sulphuric acid is obtained (1) from the gases generated by burning iron pyrites (FeS₂), (2) from the sulphur deposits of Louisiana, Sicily and elsewhere, and (3) to a very limited extent from the waste gases given off by sulphide smelters. At the present time pyrites is the most important source, but it is probable that smelter gases will be utilized to a greatly increased extent in the future, and they may eventually compete with pyrites. The sulphur dioxide that is now wasted by discharging the fumes into the atmosphere is as a rule used as a more than supply the United States with sulphuric acid. Moreover, the fumes are exceedingly objectionable, and they are destructive to vegetation.

The fundamental principles in the manufacture of sulphuric acid are (1) to oxidize sulphur or a suitable sulphide, so as to obtain sulphur dioxide, SO₂; (2) to further oxidize this to the trioxide, SO₃; and (3) to effect the combination of the trioxide with water, in accordance with the equation $\text{SO}_3 + \text{H}_2\text{O} = \text{H}_2\text{SO}_4$. In attempting to carry out the second of these processes, however, we are confronted by the fact that sulphur dioxide does not readily take up oxygen, so as to become completely converted into the trioxide. To effect this oxidation we are in fact compelled to resort to one or the other of two expedients: (1) To mix a certain amount of an oxide of nitrogen with the sulphur dioxide, and air — the oxide of nitrogen being as a rule "carrier," taking up oxygen from the air and passing it on to the sulphur dioxide; or (2) to subject a mixture of air and sulphur dioxide to the action of a suitable catalyst. The first of these expedients is used in the "chamber process" and the second in the "contact process."

The first step in the manufacture of sulphuric acid is to provide a suitable supply of sulphur dioxide gas. This is usually obtained by burning sulphur or iron pyrites in a special furnace and considerable skill and considerable care are required in this part of the operation, to obtain gases of proper composition. It is also important to minimize the quantity of dust that the gases carry over into the later parts of the process. Settling chambers, baffle plates, centrifugal separators, parallel-plate separators, and filtration through piles of marbles or other loosely aggregated solid lumps are among the devices used for the removal of the dust.

Chamber Process.—In manufacturing sulphuric acid by the "chamber process," the hot gases from the burners (consisting of air, sulphur dioxide and moisture) pass first over "niter pots," which contain nitrate of soda and sulphuric acid, and which give off the nitric oxide gas that is to act as an oxygen carrier. Then, after passing through the dust-removing apparatus, the gases are passed upward through a tower (technically known as a "Glover tower") that is loosely filled with fragments of coke, pumice, acid-proof stone, or other inert material to distribute the flow, and here they are met by a downward stream of aqueous sulphuric acid obtained from a later stage of the process, and the oxides of nitrogen in solution. The precise reactions that occur cannot be discussed here, partly because they are complicated, and partly because they are not fully understood. The general effect, however, is to oxidize the SO₂ to SO₃ and the downward-flowing stream of weak acid dissolves the SO₃ and thereby becomes stronger. In certain plants of recent design the oxidation of the sulphur dioxide and the absorption of the resulting trioxide are carried out in a series of Glover towers, without the use of chambers of any sort; but it is usual, after the gases have passed through one or two Glover towers, to cause them to enter large lead-lined chambers, from which the process takes its name. In such a chamber, more than supply the United States with sulphuric acid. Moreover, the fumes are exceedingly objectionable, and they are destructive to vegetation.

The liquid sulphuric acid settles in the bottom of these chambers, and is drawn off from time to time. Steam or water is sprayed into certain of the chambers, as needed, to provide the H₂O that is required for the formation of the H₂SO₄. The gases coming from the last chamber are passed up through a "Gay-Lussac tower," which resembles the Glover tower in general construction. The liquid that is sent down through this tower, however, is concentrated sulphuric acid, and its purpose is to absorb the nitric oxide gas that is present, thereby preventing its loss and diminishing the quantity of nitre that must be used in the early part of the process. Upon leaving this tower the gases (which then consist mainly of nitrogen and oxygen) enter a stack and pass off into the atmosphere. The acid that is drawn off from the bottom of the final Gay-Lussac tower contains excess of nitre, in solution, and is introduced (diluted, if necessary, with weaker acid) into the tops of the Glover towers. As the acid passes down through a Glover tower, however, the heat due to the reactions that occur, added to that which the entering gases already possess, drives off the nitrous oxides, and these keep returning upward through the tower with the sulphur oxides and air, while acid nearly free from nitrous oxides comes away from the bottom of the tower and is judged.

Sulphuric acid, as made by the chamber process (and especially when made from pyrites) is likely to be contaminated with lead, arsenic, nitrous oxides and many other substances. Certain of these may be removed in considerable measure by treatment with sulphuric acid. If an acid of high purity is required, however, it is better to make it by the contact process, presently to be described. When treated with sulphuric acid for the removal of metal impurities, the acid have a greater specific gravity than 1.4, corresponding to about 50 per cent of actual H₂SO₄, and must be diluted to this strength if
it is already stronger. After the removal of the arsenic the purified acid is concentrated by evaporation if a strong product is required. The evaporation may be carried out in leaden pans, set over a centigrade thermometer, recording the concentration in platinum stills. Owing to the high cost of platinum, however, it is common to perform the evaporation in a series of evaporating dishes constructed of fused silica. These are arranged like a flight of steps, the lip of each one projecting out over the next dish below. A slow stream of acid is kept running down through the cascades of dishes, while heat is applied to each dish from below. When an apparatus of this kind is properly arranged and operated it gives excellent results. Hoods should be arranged over the dishes, however, to take up the vapors that are given off and dispose of them in some proper way.

The Contact Process.—In the contact process for the manufacture of sulphuric acid, the sulphur dioxide is caused to combine with the oxygen of the air by bringing the mixed gases into contact with finely divided platinum, or with platinized asbestos. The catalytic action of platinum (that is, its power of inducing one combination in this way, without being itself consumed or otherwise permanently affected) was discovered by Sir Humphrey Davy, in 1818; and in 1824 Dobereiner showed that finely divided platinum can effect the ignition of a jet of hydrogen, when this gas impinges upon it in contact with air. Peregrine Phillips, of Bristol, England, first produced sulphur trioxide by utilizing the catalytic effect of finely divided platinum upon a mixture of oxygen and sulphur dioxide, taking out a patent for this process in 1831; and Schneider, in 1848, made a working model of an apparatus for manufacturing sulphuric acid by this method. Since that time many attempts have been made to make the contact process practicable for the manufacture of sulphuric acid, and many other catalytic agents have been tried besides platinum. It was not until about 1898, however, that the various practical difficulties involved in the process were satisfactorily overcome, largely through the labors of Herr Knietsch of the Badische Anilin- und Soda-Fabrik, a German company for the manufacture of chemical substances of nearly every kind. It was found that the prime condition of success in the application of the contact method is that the gases that are treated shall be absolutely free from dust, arsenic, mercury and certain other substances. The gases from the pyrites-roaster are cooled very slowly and are then purified by filtration and washing. When passed to the tubes containing the platinized asbestos that is used as the catalytic agent, 100 volumes of the roaster-gas contain 7 volumes of sulphur dioxide, 10 volumes of oxygen and 83 volumes of nitrogen (from the air). The catalytic platinum is maintained at a temperature of about 750° F., since it is found that at this temperature the production of sulphur trioxide is about 98 per cent of the theoretical production. The nitrogen that is present has no influence upon the reaction, when the apparatus is working properly. The sulphur trioxide that is produced by this method needs only to be dissolved in previously prepared sulphuric acid containing more or less water, in order to yield an acid that is quite pure. It might naturally be supposed that water would be the best absorbent for the trioxide; but it is found that an acid that contains from 97 to 99 per cent of H₂SO₃ is the best absorbent; and in the practical conduct of the process the trioxide is absorbed by an acid of this strength; the stronger acid that its solution yields being continuously drawn off and continuously replaced by fresh supplies of the 97 to 99 per cent acid, except when fuming acid of a very high degree of concentration is wanted. The minute details of the contact process are trade secrets and are carefully guarded.

The standard work on sulphuric acid manufacture is Lunge's "Sulphuric Acid and Alkali." Very good general accounts will be found, however, in Rogers' "Manual of Industrial Chemistry" and Thorp's "Outlines of Industrial Chemistry."

Allan D. Risteen.

SULPHURIC ETHER. See Ether.

SULPHURIC ACID, an acid having (probably) the formula H₂SO₃, and prepared by dissolving sulphur dioxide gas (see Sulphur) in water to saturation; the acid being formed by the union of one molecule of the dioxide with one molecule of water, according to the equation SO₂ + H₂O = H₂SO₃. Sulphuric acid has never been isolated, and is known only in its aqueous solution, in combination with bases in the form of the salts known as "sulphites," and as a solid hydrate. At 70° F. water dissolves about 35 times its own volume of sulphur dioxide; the solubility being greater at lower temperatures, and less at higher ones. When an aqueous solution of sulphuric acid is cooled below 41° F., a crystalline hydrate of the acid separates out, the composition of which is not definitely known. Sulphuric acid has the taste and smell of sulphur dioxide gas, and is strongly acid. It readily gives off sulphur dioxide gas, and upon standing in contact with the air it gradually absorbs oxygen and becomes converted into sulphuric acid. Its composition is also modified by the action of light, probably by the formation of a more complex oxy-acid of sulphuric acid, combining with the oxides, hydrates and carbonates of many of the metals to form salts (that is, sulphites) which are readily decomposed by the addition of stronger acids, with the liberation of sulphur dioxide. It is used in the bleaching of silk and wool but not so much as formerly, having been largely displaced by hydrogen peroxide. When the hydrogen atoms of the acid are both replaced by a metallic base, the resulting salt is called a "normal sulphite," and when only half of the hydrogen of the acid is so replaced, the salt is called an "acid sulphite," or a "bisulphite." Both of the sulphites of sodium are extensively used in photography; the normal sulphite having the formula Na₂SO₃·H₂O, and the acid sulphite the formula H₂Na₂SO₄. (See PHOTOGRAPHY). Industrially, the bisulphites of calcium and of magnesium are of exceeding importance, since the aqueous solutions of these substances possess the power of dissolving the gummy matters by which the pieces of wood are cemented together. Upon this property, the "sulphite process" for the
SULPICIANS, SUL-pish’-tən. See Orders, Religious.

SULPICIUS SEVERUS, SUL-pish’-ús say-vehr’-əs, Roman ecclesiastical writer; b. Aquitania, 363 A.D.; d. Marseilles, between 410 and 429. He was from a family of high rank and in the practice of the law at Toulouse attained a great reputation for learning and eloquence and led a gay though charitable life. The death of his wife led him to more serious pursuits. Having entered a monastery, he spent some years in preparing an abridgment of the scriptural narrative, which from the purity of its style was long a favorite textbook in the schools of the Middle Ages, but is liable to the charge of serious tampering with the facts, arising in part probably from the desire to rehuke in this guise some contemporary rulers. He continued this history, describing the destruction of Jerusalem and bringing the narrative down to his own time, under the title of 'The Chronicle of Sulpicius Severus,' in which he varies materially from Josephus. His other works are 'Life of St. Martin,' Bishop of Tours; 'Three Dialogues' and a collection of letters. From the elegance of his Latinity he was called, not undeservedly, 'the Christian Sallust.' His works have been often printed.

SULTAN, in Arabic, signifies monarch, ruler. The title is borne by various Mohammedan rulers, while the Turkish emperor assumes the title of Sultan-es-selatin, 'Sultan of Sultans.' The daughters of the sultan have also the title of sultan. The title of sultana is given out of Turkey to the chief concubines of the sultan, but no such title is in use for them in Turkey. If the mother of the sultan is living she is styled Sultan Valide.

SULU, soo-loo', or JOLO, hō-lō', Philippines. (1) An archipelago, consisting of over 400 islands, forming the southern central portion of the Phillipine Archipelago, lying between the parallels 4° 30' and 121° 52' N. lat. and the meridians 119° 25' and 121° 52' E. long.; area 1,029 square miles. The archipelago is surrounded by the Sulu and Mindanao seas on the north and west, and the Celebes Sea on the south and east. The islands form a long chain extending from northeast to southwest and are divided into five principal groups: (1) Balangungui; (2) Pagturiyang; (3) Sulu; (4) Tapul; (5) Tawi Tawi. The larger islands are generally high and of volcanic formation; the smaller islands are low and rest on coral; mountain chains traverse the islands of Sulu and Tawi Tawi. The larger islands are fertile; rice, coffee, chocolate, corn, hemp, saffron, indigo, sesame and cotton are cultivated, but not as a rule for export. The raising of horses, cattle and goats is an important industry; there is some metal working in the manufacture of chisels, knives, etc., and weaving for home consumption. The chief industry from the commercial standpoint is pearl and pearl shell fishing, large quantities of pearl shell especially being exported; other exports are shark's fins, beche de mer and native cordage. The trade is largely Chinese. The forests contain many of the most valuable woods of the East. The people of the archipelago are divided into four groups, according to their origin and customs: (a) The Guimbañanos, the aborigines living in the mountains; (b) the Malay and Visayan races; (c) the Samalés; (d) the Moros proper, the dominating race. Mohammedanism is the prevailing religion; polygamy and slavery are recognized institutions. Piracy was formerly a regular occupation of the Moros, depredations were carried as far as Singapore. (See Moros). Spain never occupied but a few towns on the coast and the native government remained largely independent of Spanish dominion. When the islands were transferred to the United States, after the Spanish-American War, negotiations were immediately begun for establishing satisfactory relations between the United States government and the sultan of Sulu and his datos (or chiefs). In August 1899 a treaty was signed in accordance with which the sovereignty of the United States over the whole archipelago was recognized, but the government of the sultan and datos continued under this supreme jurisdiction, the rights and religion of the Moros to be preserved. The following important stipulations: the United States shall occupy and control such parts of the archipelago as public interest demands; any person can purchase land with the sultan's consent; piracy shall be suppressed; the Moros courts shall have jurisdiction except between Moros; the American government shall protect the island against foreign aggression. Pop. (estimated) 22,080. (2) A group of islands in the central part of the Sulu Archipelago, lying between the Balangungui group on the north and the Tapul group on the south; area 380 square miles. All of the larger islands of this group are volcanic, each of them being formed of a central peak sloping to a narrow stretch of level coast land; the islets are generally rocks. All the staples of the archipelago are cultivated; a small amount of hemp and indigo is exported; but cattle raising and fishing occupy a larger number of the inhabitants. The trade between the islands is by native craft; the port of export is the town of Sulu. Pop. 14,500. (3) An island, the central and largest one of the Sulu group; area 333 square miles. It is traversed from northeast to southwest by three nearly parallel mountain chains, between which lie fertile valleys; there are several important peaks, of which the highest has an elevation of 2,894 feet. There are numerous small streams; which are nearly or completely dry during the summer season. The climate is particularly good, the temperature being even and unusually cool for the latitude. The soil is fertile and is well cultivated; rice, however, is imported and the chief articles of export, as in the rest of the Sulu Archipelago, are the products of the fisheries. The mountains are heavily wooded and valuable cabinet woods are also among the exports. Under the American jurisdiction, a school has been established on the island. (4) A town, capital of the Sulu Archipelago, situated on the SW coast of the Sulu Island, 540 miles south of Manila. It was the ancient residence of the Sulu sultans, but scarcely a trace of the ancient Moro town remains; the present town was built in 1878 by the Spanish and is surrounded by walls within which the town is regularly laid out, with three principal streets, broad and well
shaded. The houses are mostly well built and there is a large modern market house. It is the chief town and chief port of the Sulu Archipelago and carries on a copious trade with Singapore and Manila, as well as a native inter-island trade. In the channel between the roadstead and Maroñas is a pearl oyster bed, which employs a large number of fishing boats and the town is the centre of this industry.

SULZBERGER, sulz'ber-ger, Mayer, German-American jurist; b. Heidelberg, Germany, 22 June 1843. During the Revolution of 1848 his father came to America with his wife and family, settling in Philadelphia in 1849. He received his early education at the public schools where he graduated in 1859 from the Central High School, being at the same time an apt pupil at home in Hebrew language and literature. On 16 Sept. 1865 he was admitted to the bar, where his career was brilliant and his commanding abilities received their recognition on his appointment as judge of the Court of Common Pleas (1895-1915), and presiding judge in 1909. Sulzberger edited The Occident for a year after its founder's death, was tendered the position of United States Minister to Turkey during President Harrison's administration but declined the honor, is prominently identified with Jewish charities and instructions, and is a trustee of the Baron de Hirsch Fund. He is the author of 'Am ha-aretz' (the ancient Hebrew Parliament) (1909); 'The Polity of the Ancient Hebrews' (1912); 'The Ancient Hebrew Law of Homicide' (1915).

SUMAC, any shrub or tree of the genus Rhus. Some species are poisonous to the touch. (See Plants, Poisonous). One of the most common innocent eastern species of America, and the largest, is Rhus hirta, the staghorn sumac, so called because its young, short branches are covered with down, in color and texture not unlike a deer's antlers in the velvet. The trees are not more than 30 feet high, but are apt to grow in clumps and have a tropical appearance, with their long pinnate leaves turning to vivid yellow and crimson in autumn. Their autumnal beauty is further enhanced by the torch-like pinnate of fruits, small drupes matted together by the crimson plush of the hairs that cover them in pyramidal bunches terminating the branches. These fruit-masses remain throughout the winter, and are a favorite food of chickadees, in spite of the fur and the acridulous taste. The sour flavor was taken advantage of by the Indians and colonists who made a cooling drink from the plant. The crimson hairs also yielded a red dye, when immersed in boiling water. The wood is yellow and handsomely veined, but is very brittle; it is, however, occasionally made into canes. The fragrant, or sweet-scented sumac (Rhus aromatica), is an aromatic leaves and large panicles of greenish, honey-scented flowers which bloom in spring and are a famous food for bees. R. glabra is the upright or smooth sumac, which is smooth and even glaucous; its leaves were added to the tobacco of the aborigines; and an efficient garden plant and a thrifty shrub. The dwarf black or mountain

sumac (R. copallina), similar in size to the above species, and like them having panicles of bloom succeeded by scarlet masses of drupes, is more bushy in character and carried by the plants in sandy or dry, almost sterile soil, and is peculiar in that the main stem of its compound leaves bears conspicuous wings between the leaflets. The latter are shining above, and pubescent beneath, and, like those of R. glabra, when dried are material for tanning, the winged fruits are, however, said to be inferior to those of the Rhus coriaria, native to and cultivated in the Mediterranean regions, which are especially valuable for tanning fine leathers, as the light-tinted moroccos. They are collected, dried, and exported in great quantities in the shape of a fine dust. The Venetian sumac, or smoke-tree, is also used for the same purpose. (See Smoke-Tree). The sumacs are very useful tree shrubs to the Indians of the western United States. The twigs of Rhus trioloba, the aromatic sumac, having small three-lobed leaves, are soaked, scraped and split, resoaked in water, and then woven into baskets, sometimes in conjunction with other materials. These light, straw-colored wishes are used probably more than any material except the native basketry. R. diversiloba, the poison-oak, although greatly dreaded by the Cherokees, who endeavor to conciliate it by addressing it as 'my friend,' does not seem to injure certain Californian tribes so much. They even use it as medicine, sometimes poisoning themselves internally by the practice, and use twigs of it as water-sprinklers in sacred ceremonies; it is also a material for woven fabrics. Its juice, which turns black rapidly on exposure to air, is utilized as an intense black dye for basketry. R. trioloba likewise yields a dye. A strong decoction of the leaves and twigs is made, to which is added roasted pinyon gum and yellow ochre, forming a rich, blue-black fluid, which is practically an ink, the tannic acid of the sumac combining with the iron in the yellow ochre, and being strengthened with the carbon of the burnt gum. The lacquer or varnish of China and Japan is nothing but the sap of another sumac (R. vernicifera), the varnish-tree, cultivated in those countries. When the bark is cut, the shrub exudes a juice, darkening after exposure. When kept for some time this sap becomes thick and viscous, blackish-brown in color in one mass, but yellow-brown and transparent in thin layers. When properly applied in successive layers and dried, it becomes a natural varnish of great hardness and unalterability. Nut galls, or iron in solution, added to this, or gold and other metals, make the various kinds of lacquer or japanning, which it often takes years to perfect. Japan wax is a vegetable wax used chiefly for candles and obtained by crushing, steaming and pressing the drupes of this species and of the Asiatic R. succedanea.

SUMATRA, soo-ma'tra, an island in the Indian Seas immediately under the equator. Its extreme limits are lat. 5° 45' N., and 5° 55' S.; long. 90° 40' E., and 106° 5' E. In the direction of its greatest length it extends from northwest to southeast. Its greatest length is about 1,000 miles, and its greatest breadth about 260 miles; its area is about 161,000 square miles. It ranks in magnitude as the second of the
SUMATRA

Asianic islands, Borneo being the first. The population is about 4,000,000.

The western side of the island is mountainous, but the east side has a totally different character, and spreads out into innumerable plains nearly as level as the sea. The mountains viewed from the west appear at first view to form a continuous ridge, but a closer examination reveals breaks in the chain, and discloses the fact that two or three ridges lie behind that which is mainly seen from the coast. This chain, known generally as Barisan, extends from the northwest of the island to Sunda Strait. The islands of Pulo Bras and Pulo Wai really form detached parts of it, and near them, at the northwestern end of the island, it attains a height of 3,663 feet in Mount Yamura. Farther south, but still in Acheenese territory, are the lofty volcanoes Abong-Abong and Lusé, whose heights are estimated at over 11,000 and 12,000 feet respectively. Mount Ophir, close to the equator, is an extinct volcano 9,610 feet above sea-level. Not far to the southeast is Mount Moba, the most visited of Sumatran volcanoes. Other notable peaks are: Talang (8,343), an extinct volcano, from which the natives obtain sulphur; Indrapura (12,000), the highest peak yet ascended in Sumatra; Mount Paung; Mount Kaba (5,413); Mount Dempo (10,562), an active volcano; and Mount Tangkamus (7,422), near the Straits of Sunda. Granite, slates, clay-chests and similar rocks abound, and limestones of Carboniferous age occupy much of the surface. Tertiary formations cover a very large area. All the peaks seem to be volcanic. Various metals have been found in the island, and excellent coal is known to be abundant.

Rivers and Lakes. The rivers that flow toward the west are naturally short and of small importance for navigation, but those traversing the broad alluvial eastern slopes are long and deep. Many of them form large deltas. In order from south to north the most important are: the Musi or Palembang, about 400 miles long, passing the town of Palembang and entering the sea opposite the island of Banka, an important highway for trade; the Jambi or Batang-Hari, over 500 miles long, and navigable throughout its entire length, is the natural outlet for the coal-fields; the Indragiri; the Kampar; the Siak, rising near Mount Ophir; the Rakan and the Batu Bara. Of the west-coast rivers the Singkel is the most important. The lakes of Sumatra are mostly mountain lakes, and not a few of them occupy the craters of extinct volcanoes. The largest are: Toba, 500 square miles in area, at the source of the Singkel River; Singkara and Marungin, about the centre of the island near the west coast; Korinchi, near Indrapura; and Danau. Sumatra is almost bisected by the equator, and in consequence the monsoons of its northern extremity have different directions from those of the southern end. During the period when the north monsoon is blowing, navigation in the neighboring waters is impeded by squalls. The climate is generally of the usual tropical character, and is on the whole rather unhealthy.

Sarawak. The flora of Sumatra differs much from that of Java. It is very rich in forest trees, many of which yield valuable timber or other useful products, such as benzoin and gutta-percha. Pepper is the chief cultivated product. Sago and rice are also cultivated, and excellent. Copra and rice are grown for export. The fauna of Sumatra in some respects resembles that of Borneo more closely than that of the countries with which it is almost in contact. The elephant and the tapir, frequent in Sumatra, are unknown in Java. The former island has the two-horned, the latter a single-horned rhinoceros. The orang-utan is found locally. The tiger occurs both in Sumatra and Java, but not in Borneo; Sumatra has also some species of deer and antelope, the sunbear, a peculiar kind of hare, and the muntjac. The most notable birds are the Argus pheasant, several trogons, bush-shrikes, rain-birds, pheasant-cuckoos, etc. Of the domesticated animals the most important by far is the pig, next to which rank the cow and the horse. The buffalo is more frequent in the low country, but is only valued as food, and never yoked for labor as in Java. The horse of the highlands is small, but vigorous and capable of enduring the most arduous work.

Government. The authority of the Dutch extends, nominally at least, over the greater part of the island, and may be considered to be real over all the coast districts. In the interior, however, there are still considerable numbers of native rulers, or forming village confederations, over which the Dutch exercise little or no authority. The Dutch possessions are divided into six chief divisions. The government of the west coast, with an area calculated at 31,649 square miles, extends along the middle portion of the west coast, and includes Padang and other districts. The governor resides at Padang. The residency of Benkulen lies to the south of that of the west coast, and has an area of 9,399 square miles, Benkulen being the capital. The residency of Lampang comprises the southern districts of the island on the Strait of Sunda, and has an area of 11,284 square miles. The residency of Palembang on the east coast, with an area of 53,497 square miles, lies to the north of Lampang, and has as its capital the large town of Palembang. The district of Indragiri, farther north, belongs to the residency of Kio, which is named after the island of that name. The residency of the east coast, its area being estimated at 35,312 square miles; and at the extreme north-west that of Achin, which still remains semi-independent, area 20,471 square miles.

Racial Characteristics. Sumatra is inhabited by a very mixed population. Malays col-lected from every quarter of the archipelago inhabit the coast. Hindus appear to have settled at an early age in the north, and to have modified the Malay type of the Acheenese. The Arabs in the island, though few in number, have always formed an important class. Chinese are numerous, particularly on the east coast. Northwest of Palembang the Orang-Kubu live in a savage state, and shun any intercourse with the white man. The Kubu must not be confounded with the people of Menankabu, a pure Malay race inhabiting the highlands of Padang, which some are disposed to consider the original seat of the Malay stock. The Batakans are a peculiar and interesting race. Like the Malayans they are of short stature, but they differ from the former in being strongly built and well proportioned. The
art of writing has been known among the Bat- 
taks from a date beyond the reach of tradition. 
Their characters are peculiar, and also their 
mode of writing, for they begin at the bottom 
of the page at the left-hand side, and place 
letter above letter in a vertical column till they 
reach the top, when they return to the bottom. 
Their ancient books are written in a bright red 
ink on paper made of the bark of trees, but 
now they scratch their writings on slips of 
flattened bamboo. Among all the indigenous 
tribes of Sumatra the characteristic political 
tendency is one that could have originated only 
in the recesses of the mountains. Every village 
affects independence, but the villages form 
federations. The native tribes of Sumatra have 
no temples and no priests. They are said to be- 
lieve in the existence of an evil spirit and of 
demons who haunt the mountains. On the coasts 
Buddhism appears to have been introduced at 
an early age, but it has since been completely 
superseded by Mohammedanism, which, among 
the Malays, however, is of a very relaxed char- 
pacter.

History.—The first European who visited 
the island of Sumatra is said to have been Nic- 
colo de Conti, who came there before 1449. 
In the beginning of the 16th century it was 
visited by the Portuguese, but no Europeans obtained 
a firm footing on the island until the Dutch estab- 
lished a factory on the west coast at the end of 
the 16th century. In 1666 the Dutch took 
possession of Padang, and soon after enlarged 
their territories by treaty with the Sultan of 
Achinn. Since that time they have gone on con- 
tinually consolidating and increasing their do-
minion much more by negotiation than by force 
of arms. Their last important accession of in-
fluence on the island was gained by a treaty 
with the king of Siaik, concluded in 1808, 
by which they obtained the virtual control of 
that state. In 1685 the British formed a settle-
ment in Bentjlen, and in 1811 they seized the 
Dutch possessions on the island. These were, 
evertheless, restored in 1824 Bentjlen 
was given over to the Dutch in exchange for 
Malacca. A treaty concluded between the Dutch and English governments in 1834 left 
the Dutch free to make what treaties they pleased with the native tribes of Sumatra, the same liberty being allowed to 
the British on the Malay Peninsula; but the 
right of the Dutch to make advances in the 
land by conquest and annexation was not 
then recognized. This right was, however, con- 
ceded in the treaty of February 1871, in return 
for the cession to the British of the Dutch pos-
sessions on the Gold Coast; and in accordance 
with this permission the Dutch despatched an 
expedition against Achinn. In April 1873, the 
forces of the two powers came into collision, 
and a war ensued which dragged on for a num-
ber of years, caused severe losses to the Dutch, 
and terminated only in the nominal subjugation 
of Achinn. In August 1883 the tidal wave that 
appeared among the islands of Krakatoa, swept with destructive effect the 
west coast of Sumatra, a total change in the 
aspect of the Straits of Sunda also resulting 
from the eruption. Consult Bernard, 'A 
time in Sumatra' (London 1903); Paston, H., 
'Sumatra' (Leipzig 1902); Cabatén, A., 
'Java, Sumatra, and the other Islands of the 
Dutch East Indies' (New York 1914).

SUMBAWA, Sumerian Languages 11

SUMBAWA, soom-ba'wa, an island be-
longing to the Sunda group, in the Indian 
Ocean, east of Java, containing 5,192 square 
miles. The island is mountainous and of ex-
traordinary profile. The volcano of Tomboro 
or Tombura, 8,940 feet high, is near the nor-
thern coast and famous for its eruptions. The 
Sunda consists of two parts, with two rulers of 
Sultans, who acknowledge the sovereignty of 
Holland. There are few streams. The chief 
products are rice, cotton, tobacco, tropical fruits 
and sappan-wood. Of domestic animals deer 
and swine are plentiful, and the finest horses 
of the Indian Archipelago are reared here, and 
exported. Edible birds' nests are found on 
the coasts; gold, silver, saltpetre and peals 
from the mines and waters, respectively. On 
the north coast there is a good harbor, and 
here stands the town of Sumbawa. The inhabi-

tants are Malays and Mohammedans. Pop. 
75,000.

SUMBUL, an East Indian name of the 
sparikenard (Mardostachys), and also of 
the valerian, but, more particularly of Ferula sumbul, 
the commercial drug also known as musk-root. 
The last is an umbelliferous herb, with deeply 
divided leaves. The roots reach the pharmacists 
in transverse segments, light and spongy in 
texture, with a thin, brown, wrinkled and fi-
brous skin, but whitish inside. The taste is 
bitter and balsamic, the odor strong and like 
musk. Sumbul is used therapeutically as a stim-
ulant and nervine, and was of importance long 
before its botanical history was known.

SUMERIAN LANGUAGES. The pris-
tine, agglutinative language spoken by the earli-
est, prehistoric people of Mesopotamia, a region 
generally referred to in surviving documents as 
mar Shumer or Akkad, i.e., land of the Sumer-
ians and Akkadians, probably the biblical Shinar 
or Shin'aar. It was a non-Semitic people thus 
dwelling in the lowlands between the Euphrates 
and Tigris, as comparative philology has of 
recent years proved beyond a doubt. True, the 
eminent French scientist, Joseph Halévy, in 
1876, and certain of his followers, contends 
for the non-existence of any such early non-
Semitic population. Halévy attempted to ac-
count for the myths and cuneiform characters 
by assuming a Semitic, priestly, secret style of writing, a cryptography, 
and cited as a parallel the Egyptian hierarchical 
writing. However, this has since been amply 
disproved. The meaning of the word Sumerian, 
or rather Shumerian, refers to the word *reed,* 
*reedy* in that idiom, evidently because of the 
marshy, reedy landscape. The Sumerians and 
the Akkadians seem to have formed one people, 
though originally they may have come from 
different parts of the earth. The Sumerians, 
at any rate, as their tongue, an agglutinative 
one, shows, must have come from the north, 
possibly the Ural region, as there were no 
words or word pictures among the phrases in it 
symbolizing fauna authentic to either of them. 

So far as the records go, the Sumerians 
were the earliest nation, and their system of 
writing, the cuneiform, is likewise the earliest 
we know of. Later on, the Sumerians, by co-
habitation and Bretemization, were amalgamated 
with the later Semitic invaders, 
Arab tribes originally coming chiefly from the 
island of Bahrain. The Sumerian tongue like-
SUMMARY COURT — SUMMER

wise coalesced in a manner with the Semitic idiom, the latter being superimposed on the former, much as the New Testament French was superimposed on Anglo-Saxon, and thus the later Babylonian was formed. Semitic civilization and language, however, were highly developed before the coming of the Semites, as well in the construction of their cities as in its religion, its religious observances, its legislation, arts, science and social life. The Semitic Babylonians imbibed the earlier civilization.

Nevertheless, the "Sumerian problem," so-called has for generation perplexed Assyriologists. Oppert, in 1854, first made modest, though in a measure successful attempts to unravel its mysteries. But Prof. Paul Haupt, assisted by Prof. Peter Jensen and Zimmern, somewhat profiting by these initial labors, steadily bewed his way through these etymological brambles, and it is strikingly illustrative of the value of Haupt's pathbreaking labors that all subsequent phonetic and grammatical work in Sumerian has only tended to confirm Haupt's views in instance. Haupt's "Sumerian Family Laws" and "Akkadian and Sumerian Cuneiform Texts" laid the foundation to all later researches. In the investigation of the Sumerian idiom no comparison should be made between Sumerian vocabularies and those of more recent agglutinative idioms, despite frequent tempting resemblances, such as in Turkish, for instance. Now and then, though, certain similarities are traceable with Estonian and Finnish. Sumerian, as far as has been shown up to the present, must be held a language standing alone by itself, a "prehistoric philological remnant."

To Prof. Friedrich Delitzsch is due the merit of having clearly shown the full meaning, the derivation and development of Babylonian cuneiform signs. They were, then, at first pure picture writing and finally grew into conventional ideographic and syllabic sign lists. The etymological labor involved in this process of gradual elucidation was surrounded with enormous difficulties.

Sumerian cuneiform was adopted at least about a.c. 7000. By a.c. 5000 we see it already highly specialized, and between a.c. 4000 and 3000 we perceive it applied to the transmission of the invading Semitic language, the Babylonian; and since then the Semitic Assyrians, the Medes, the Turanian Susites, and the Caucasian Armenians have all habitually used the cuneiform.

Besides other evidence tending in the same direction, perhaps the most convincing proof, from a philological point of view, that ancient Sumerian was a real idiom, of natural growth and wholly unartificial, may be found, aside from the internal phonetic changes, in the indubitably established fact that there were two dialects of it. These were the Emesal, the man's language, the noble, virile, though harsh form, and the Emenal, the woman's language, the softer. There were no geographical boundaries to these two dialects. In R. E. Brunton and C. F. W. Fairweather's "A Dictionary of all Simple and Compound Ideographs" (1889), it is also demonstrated that the Sumerian original idiom was of unaided growth. He and others point out that there were probably eight voice tones employed in Sumerian, similar to the Chinese of to-day, and that the intonation often determined the meaning. As a possible illustration may be cited: aβewith, moisture, dew, tears, inundation, irrigation; abβ—dwellings, sea, road, and a grammatical suffix.

After Sumerian had ceased to be a living tongue it was, up to a very late period of Babylonia's existence, greatly used as a ritual one, and was read aloud at worship in the temples, much as is, for example, early Slavonic in Russian and other Orthodox churches to-day.

SUMMARY COURT. See LAW, MILITARY.

SUMMARY PROCEEDINGS, in legal form of trial in which the ancient established course of legal proceedings is disregarded, especially in the matter of trial by jury. In no case can a party be tried summarily unless when such proceedings are authorized by legislative authority, as in a committal for contempt of court, the conviction of a person by justices of the peace, etc.

SUMMER, the season of the year which in the northern hemisphere generally may be said to comprise the months of June, July and August. The astronomical summer lasts in the northern hemisphere from the June solstice to the September equinox, during which time the sun, being north of the equator, shines more directly upon this part of the earth, and rises much sooner and sets later, which renders this the hottest period of the year. The period of greatest heat generally takes place in August, since the influence of the sun's rays has then been felt for a long time on the earth, and the winds are blowing to a moderation of the temperature in the polar circle caused by the thawing of the ice. In the southern hemisphere the summer lasts from the December solstice to the March equinox.
SUMMER DUCK—SUMMER SESSIONS

SUMMER DUCK. See Wood-duck.
SUMMER REDBIRD. See Tanager.

SUMMER SCHOOL OF THE SOUTH, a school for teachers established at the University of Tennessee, Knoxville, in the summer of 1902. It was organized to supply the ever-increasing demand on the part of southern teachers for a summer school of high grade and adequate equipment for the best normal training. It receives its financial support from the General Education Board, from the University of Tennessee, from the citizens of Knox County, and from individual donations; the registration fee is small. All the buildings and full equipment of the university are given to the use of the school. The courses number over 150. The work is arranged in the following groups: (1) Common school and primary grades; (2) psychology and pedagogy; (3) high school and college subjects; (4) rural schools and county supervision; (5) city school supervision; (6) general lectures; (7) professional exhibits; (8) conferences. Teachers have free choice of subjects, but are advised not to take work for more than three or four periods a day. The instructors and lecturers are men and women of recognized scholarship and authority, coming from various institutions and different sections of the country. The school has a large attendance and has proved a marked success.

SUMMER SESSIONS. The summer school responds to a specific need. Professional people such as teachers, ministers, doctors, and other workers like social workers, Y. M. C. A. and Y. W. C. A. secretaries and even business men and women, find the summer vacation period a suitable time to undertake advanced educational work in specially selected subjects. The other seasons of the year are devoted to exhausting labors; the summer study is both recreative and inspirational and may be made to contribute to professional advancement. When systematically planned and extended over a period of years, summer work may even have recognition in the form of academic credit or academic degrees.

Of the persons listed above teachers in service make the most insistent demand for summer courses. New methods and new educational movements continually call for special short courses. For example, the Montessori method, or the Direct Method in Latin, may be studied to advantage in this way. Teachers may add to their regular accomplishments certain special, perhaps new, activities, such as domestic science and art, various phases of handwork, craftwork, physical education, elocution, etc. Again, a famous teacher from a foreign land may offer courses during a summer session, affording attractive opportunity for special investigation, or for getting a particular method or a particular form of interpretation in a known field. It is a growing practice among municipal school authorities to offer special inducements to public school teachers to take summer courses. The elementary teacher more particularly, but the high school teacher also to some extent is tempted to stagnate. After teaching the same subject several years, the dull monotony of the process deadens the ambition. This is especially true where knowledge of method is more important than knowledge of subject matter as in the elementary school. The opportunity for summer study is especially inspiring in such cases. Physicians also find it desirable to investigate new treatments, to observe and learn new methods in surgery, to get a new point of view in the profession. The summer session or clinic may give the desired opportunity to the farmer demands special opportunities for the observation of special methods and practices and looks to a short session of the Agricultural College to supply his needs. In this case, however, the winter may offer greater advantages.

Recently efficiency experts have advocated the continuous use of educational plants. The idle recitation halls, laboratories and libraries are considered uneconomical. This idleness may continue from 15 June to 15 September, 25 per cent of the educational year. Apparently this record only 75 per cent efficiency for faculties, plants and investments. For the faculty the inefficiency is only apparent since the fall months are essential to the increase in fertility and resourcefulness of the plant, however, and of the invested funds, the charge of inefficiency is partly true. If a separate faculty can be provided to use the equipment during the summer, a faculty that has its fall months at another season of the year, then an all year program becomes efficient.

The Four-Term Year.—A continuous session plan was devised at Chicago University by President William Rainey Harper, who stated that institution was first opened in 1892. It provides (1) four terms of twelve weeks each; (2) twelve terms completed work are required for graduation; (3) a student may complete twelve terms in three years; (4) that a student may select any three terms, as a year's work, devoting the other term to rest or business; (5) that a member of the faculty may elect to be absent from college duties during any one term of any calendar year.

This plan accomplishes at least that summer sessions usually seek to do and much more. (1) It incorporates the summer session as an integral part of the academic year. The summer term differs in no essential respect from any of the other terms. (2) Students may begin their college or university courses four times each year. (3) The university equipment is in continual use. (4) The university can use the best men from other institutions in this country and even from foreign universities.

The continuous session plan or the four-term year is the logical development of the summer school movement. Its sponsor, Chicago University, has used it continuously from 1892 to 1918. A quarter of a century has tested the plan thoroughly and has justified it. That few other colleges and universities have adopted it is no argument against it. It seems probable that acquaintance with its features and its satisfactory results will gradually lead to a wide if not universal use of it.

History of Summer Schools.—The Concord School of Philosophy was proposed by Ralph Waldo Emerson as early as 1840 and came to full fruition between 1879-85. The Harvard Summer School has lived from 1869
to the present. The Chautauqua Summer School began in 1874. A summer school of law was opened in 1870 by the University of Virginia. From these beginnings have grown institutions not only of most of the colleges and universities conduct such schools but Chautauqua schools. Y. M. C. A. and Y. W. C. A. schools, music schools, tutoring schools, normal schools, library schools, etc., are meeting the growing demand for summer school facilities. According to the latest report (1916) of the United States Bureau of Education 674 schools were in session during the summer of 1915, 47 universities, 40 colleges, 90 normal schools, 39 other institutions, 456 independent schools.

All colleges and universities listed offer academic credit for work completed in the summer session. Of 90 normal schools listed, only 46 offer credit. The basis for such credit is 30 hours of recitations, implying 60 hours of preparation for each credit-hour. A student may usually earn four credit-hours in one summer session. Since a college year is given 15 credit-hours, it will require four summer sessions to earn a full credit-year.

The process is, therefore, slow, but thousands of students persist until they earn the coveted credit-year. Especially is this true of students whose college course was interrupted and who in this way complete work for the bachelor's degree; and many college graduates take this means of earning a master's degree.

**A. R. BRUBACHER, President of State College for Teachers, Albany, N. Y.**

**SUMMERS, George William:** b. Fairfax County, Va., 4 March 1807; d. Charleston, W. Va., 18 Sept. 1868. He entered Ohio University at Athens, Ohio, in 1819 and graduated in 1825. He then studied law and was admitted to the bar in 1827. In 1830 he was elected a member of the lower house of the Virginia legislature and was later re-elected several times. In 1841 he was elected to the United States House of Representatives, and was re-elected in 1843. In 1850 he was elected to the Virginia Constitutional Convention and took a prominent part in framing the new constitution. In 1851 he was the Whig candidate for governor of Virginia, in the first popular election for governor in Virginia, but was defeated by Joseph Johnson, the Democratic nominee. In May 1852 he was elected judge of the eighth judicial circuit of Virginia, but resigned his office 1 July 1858. He was a prominent member of the *Peace Conference* held at Washington in the spring of 1861 and took an active part in defense of the Union. He was also elected a delegate to the Richmond convention which passed the Ordinance of Secession. In the convention he made an able speech in defense of the Union. At the opening of the Civil War he retired to private life upon his farm but continued to accept one and later was sent to be a member of the peace commission. He wielded a large influence in western Virginia.

**SUMMERS, Süm'ers, Thomas Osmund, American Methodist Episcopal (South) clergyman:** b. near Corfe Castle, Dorsetshire, England, 11 Oct. 1812; d. Nashville, Tenn., 6 May 1882. In 1830 he came to the United States where he studied for the ministry and was admitted to the Southern Conference in 1835. He was active in the organization of the Texas Conference, 1840, and later was sent to the Alabama Conference. He was professor of systematic theology at Vanderbilt University, dean of the faculty and pastor ex officio of that university. He has published *Commissions, Rituals, and the Gospels; the Ritual of the Methodist Episcopal Church (South); 'Seasons, Months and Days'; 'Talks, Pleasant and Profitable.' Consult *Life* by Fitzgerald (1894).

**SUMMERSIDE, Canada, town and port of entry of Prince Edward's Island, capital of Prince County, on Bedeque Bay and on the Prince Edward's Island Railroad. It is 40 miles northwest of Charlottetown and has an excellent harbor with anchorage for the largest vessels. There are flour and saw mills, manufactures of plows, etc., and it is the centre of the recently developed fox ranch industry. Summerside has regular communication in summer by steamer with Nova Scotia and New Brunswick. Pop. 2,678.**

**SUMMERSVILLE, Ga., city in Richmond County and suburb of Augusta. It lies in a fertile valley 25 miles north-northwest of Rome, on the Central of Georgia Railroad. On account of its mild winter climate it is a popular winter resort. It contains a government arsenal and ordnance department. Pop. 4,901.**

**SUMMIT, N. J., city in Union County, on the Delaware, Lackawanna and Western Railroad, 20 miles west of New York and 12 miles west of Newark. It is in an elevated part of the county, about 450 feet above tide water. Summit was settled in 1795, and the first school was built the same year. The first church building was erected in 1840. It was incorporated as a township in 1859 and as a city in 1899. It is a purely residential community, noted for its beautiful rural and suburban climate. The chief industries which contribute to the prosperity of the city are manufacturing silk goods, cultivation of roses, farming and the cultivation of fruit. Summit is a residential city, and has many New York and Newark business men among its inhabitants. The municipal improvements include gas and electric lights, pure water, an excellent tide water sewerage system, well-organized police and fire departments, free postal delivery and telegraph and telephone service. There are eight churches, Y. M. C.A. building and the Arthur Home for Blind Babies under the International Sunshine Society. The educational institutions are Kent Place School, for girls; Summit Academy, for boys; five public schools, one parish school and a free public library. The two banks have a combined capital of $200,000. The government is vested in a mayor and a council of seven members, who hold office for three years. Pop. 9,136.**

**SUMMONS, in law, an admonition to appear in court, addressed to the defendant in a personal action. It is the writ by which a personal action is always commenced. According to English law it need not state the form or cause of action, but it must contain the names of all the defendants, and must have endorsed
upon it the name and address of the person taking it out, whether the plaintiff himself or his attorney. It is the duty of the person taking out a summons to serve it on the defendant in person; but if the judge is satisfied that reason and good conscience requires it, and that the defendant knows that the summons has been issued against him, he may authorize the plaintiff to go on with the action without personal service.

SUMNER, Charles. American statesman; b. near Haverhill, Mass., Jan. 8, 1811; d. Washington, D. C., March 11, 1874. His family was English in origin, Charles being a descendant in the seventh generation from William, who came to America about 1635 and settled at Dorchester, Mass. The Summers lived in the same vicinity for the next 200 years and more, generally as farmers. The father, Charles Pinckney Sumner (b. 1776; d. 1839), graduated from Harvard in 1796. He was a lawyer, was married to Relief Jacob of Hanover, N. H., in 1810 and had nine children, of whom Charles was the eldest. The father took an active interest in politics, was clerk of the Massachusetts House of Representatives in 1806–07 and 1810–11 and from 1825 to 1839 was sheriff of Suffolk County. He was noted for his temperance and in 1811 armed himself and was strongly anti-slavery in feeling. He was fond of books, conscientious, earnest, grave and stern. It was not strange, then, that he brought up his son in the old Puritan style and the latter's career shows that he was greatly influenced by his father's teaching, views and character.

Charles was educated at the famous Boston Latin School, having as schoolmates Robert C. Winthrop and Wendell Phillips. His tastes were those of the scholar and he read widely and became proficient in the classics. He entered Harvard College in 1826, where he continued to excel in the classics, but also devoted much time to history and literature and perfected himself in oratory or declaiming. After a year spent in private study and diligent attendance on the lectures and orations of the great Boston orators, Webster, Everett, Choate and Calhoun, he entered the Whig Lyceum School in 1831 and received the personal attention and teaching of Judge Story, an old friend of Sumner's father. His plan of study was thus described in a letter to a friend: "Six hours, namely, the forenoon, wholly and solely to law; afternoon, classics; evening, history, subjects collateral and assistant to law, etc. Recreation must not be found in idleness or loose reading." In January 1834 he entered the law office of Benjamin Rand in Boston. In February he made a journey to Washington, where he received his first impressions of slavery in the South. His first subscription for a newspaper was for Garrison's Liberator. While in Washington he heard Webster, Clay and Calhoun deliver in the Senate, but he still thought he preferred law to politics. During the next three years, 1834–36, he practised law in Boston, but without remarkable success. His arguments were in the nature of learned essays rather than the public orations of the case in a manner to convince jurors.

In 1837 he went abroad and spent three years traveling in France, England, Italy and Germany. In Paris, where he lived five months, he attended university lectures, visited the museums, galleries and historic places, attended the Chamber of Deputies and law courts, went into society and met many eminent persons. He next spent 10 months in England and met the famous men of the day, Carlyle, Wordsworth, Macaulay, and many of the best Italian literature. Then he spent several months in Germany and finally returned to America in May 1840. His foreign travel unfitted him for his chosen profession, to some extent, and still further intensified his longings for the scholar's career.

During his absence abroad the slavery question had become a burning issue, though up to this time he had but slight interest in politics or in the great public questions of the period. From 1841, however, his letters commence to show evidence of more positive views on the slavery question and more determination to oppose the further spread and influence of this institution. His humanitarianism showed itself in his interest in popular education and in the support of Horace Mann, in the work for the blind, in that for the improvement of prison discipline and in his opposition to war under all circumstances. In 1843 he commenced to/utilize against slavery, and contended, in opposition to many, that it was a national rather than merely a local evil: that the nation was responsible and that it might to a large extent remove the evil by abolishing slavery in the District of Columbia and in the Territories, by compelling the rendition of fugitive slaves, by preventing the slave trade, by remedying the laws of slave States which abridged the right of free negroes in free States, by stipulating the conditions of admitting new States and by amending the Constitution so as to abolish slavery. Sumner made his real débüt in public life by a Fourth of July oration in Boston, 1845, on the "True Grandeur of Nations," in which he bitterly denounced wars of all kinds as dishonorable. Four months later he made his first anti-slavery speech at a meeting in Faneuil Hall to protest against the annexation of Texas.

In 1846–47 Sumner made several speeches in favor of the Whig party and was afterwards a general slavery attitude. He wrote for the newspapers against the Mexican War; declared that it was unconstitutional, unjust and detestable, opposed further expenditures for it, called for the withdrawal of troops and opposed the annexation of the territory to be acquired from Mexico to slavery. He joined the Free Soil party of 1848 and was nominated for Congress in October, but failed of election. When Webster, in his speech of 7 March 1850, refused to vote to exclude slavery from California and New Mexico, he became, in the eyes of many in Massachusetts, an apologist of slavery and this situation opened the door of the Senate to Sumner.

In Massachusetts the autumn campaign hinged on the question whether the State should approve the Compromise of 1850 and the course of Webster in supporting it. There was bitter opposition to the Fugitive Slave Law and the manner of its enforcement. Sumner made an important speech in Faneuil Hall 6 November against the Fugitive Slave law and demanded its repeal. This speech made possible his election as senator in January 1851, for in the State election the combined Democrats and
Free Soilers had a majority of the legislature and chose Sumner rather than Winthrop, the Whig candidate, as senator. With the entrance of Sumner into the Senate, a new force for anti-slavery agitation was present. He was an uncompromising, fiery, earnest, and persistent antagonist of slavery. He was the spokesman of the anti-slavery forces in the Senate as Calhoun was for the pro-slavery interests. Although the leaders of both parties were for peace, Clay and Webster on one side and Cass, Buchanan and Douglas on the other, nevertheless Sumner believed that the Compromise of 1850 was wrong and that "nothing can be settled which is not right." It was not until August 1852, after both the Whig and Democratic National Conventions had declared their support of the Compromise of 1850, that Sumner spoke of the great question, viz., "Freedom National, Slavery Sectional." His argument was to the effect that slavery was not recognized in the Constitution, that Congress had no power to establish it and that, therefore, it could not legally exist where the jurisdiction of Congress met; that the Fugitive Slave Law was unconstitutional and, therefore, should not be obeyed. This speech made Sumner the leader of the anti-slavery party and his doctrines were accepted as sound by a rank and file.

The next Congress, that commencing 5 Dec. 1853, was made famous by the passage of the Kansas-Nebraska Bill, which was designed to repeal the Missouri Compromise. It was on 23 Jan. 1854 that Senator Douglas introduced a bill dividing the Nebraska Territory into Kansas and Nebraska. This bill declared that the Missouri Compromise was superseded by the principle of the legislation of 1850, commonly called the compromise measure, and is hereby declared in operation. Sumner spoke against the bill 15 Feb. 1854 and declared that the Missouri Compromise was a binding contract. His speech on 26 June in reply to an attack on Boston and Massachusetts by Southerners, particularly Sen. Butler of South Carolina and Mason of Virginia, aroused great feeling.

The passage of the Kansas-Nebraska Act led to the formation of the Republican party. A Republican convention, composed mostly of Free Soldiers, was held at Worcester, Mass. 7 Sept. 1854 and Sumner spoke for the new party. He advocated resistance to the enforcement of the Fugitive Slave Law and advised the passage of personal liberty laws to nullify its workings. He justified his position by denying that the provision of the Constitution touching the rendition of persons held to service or labor was conferred any power on the national government to establish uniform rules for the rendition of fugitives; that therefore, each State had the right to determine for itself the extent of the obligation assumed. In consequence the Fugitive Slave Law was unconstitutional and the States had a right to act in December 1853 in rendering a fugitive slave the right of trial by jury and the privilege of habeas corpus. This view would give the States liberty to construe the Constitution and pass laws which their construction of the Constitution permitted. In case there was a conflict between the Supreme Court and the States in the construction of the Constitution, then no man "will voluntarily aid in enforcing a judgment which in conscience he believed wrong." This was preaching revolutionary doctrine and was the most violent and extreme position which Sumner had taken up to this date.

In the second session of the 33d Congress, that commencing December 1854, Sumner endeavored to forestall the legislative re-enactment of the Fugitive Slave Law, but was defeated. In the spring of 1855 he prepared an address entitled "The Anti-Slavery Enterprise, its Necessity, Practicability, and Dignity, with Glances at the Special Duties of the North." This was delivered in Boston, New York and other places.

It was in this address that he prophesied the downfall of slavery because of a "moral blockade" against it. With the sympathy of all Christendom as allies, already it (Anti-Slave movement), encompasses the slave masters by a moral blockade, invisible to the eye, but more potent than navies, from which there can be no escape except in final capitulation. Two of the great events of the session of Congress that met in 1855 were Lincoln's speech of 19 and 20 May 1856, on "The Crime against Kansas," and the assault on him by Representative Brooks of South Carolina. It was on 12 March 1856 that Senator Douglas reported a bill for organizing a State government in Kansas. This provided that the steps taken should be prescribed by the territorial legislature. This was the pro-slavery legislature which had been elected in March 1855 as a result of fraudulent votes which had entered Kansas for this purpose. Congress had to decide whether it would recognize this legislature or admit Kansas as a free State under the Topeka constitution, which had been formed by the free-state men in the convention which met at Topeka 23 Oct. 1855.

The debate on the subject began 20 March and continued for some months. Conditions in Kansas had been going from bad to worse and pro-slavery troops had been disarming free-state settlers, and finally, on 21 May, they made an attack on Lawrence, demanded the surrender of all arms, broke the presses of the newspapers, burned the Free State Hotel and plundered houses and dwellings.

It was under such circumstances that Sumner delivered his famous and carefully prepared speech which he meant to be the most thorough philippic ever uttered in a legislative body. In this speech he reviewed the whole case from the passage of the Kansas-Nebraska Bill up to the time of the attack on Lawrence. He criticized the administration and attacked his opponents in the most bitter language, especially Senators Butler of South Carolina and Douglas of Illinois. The former had chosen a mistress to whom he made his vows, and who, though ugly to others, is always lovely to him; though polluted in the sight of the world, is chaste in his sight; I mean the harlot Slavery. Douglas had used language and doctrines which brought forth the reply that "no person with the upright form of a man" could be allowed to switch out from his tongue the perpetual stench of offensive personality. Sir, that is not a proper weapon of debate, at least on this floor. The noisome, squall, and nameless animal to which...
I refer is not the proper model for an American senator. Will the senator from Illinois take notice? These bitter personalities led to the order by President S. Brooks, a representative from South Carolina, and a cousin of Senator Butler. The Senate had adjourned and Sumner was seated at his desk writing letters, when Brooks entered and said, "Mr. Sumner, I have read your speech to the Senate and I am here to destroy it, as was possible, and I feel it my duty to tell you that you have libeled my State and slandered a relative who is aged and absent, and I am come to punish you for it." He then struck Sumner a series of blows on the head with a guita percha cane, until he fell bloody and senseless to the floor. An effort to expel Brooks from the House failed because of lack of two-thirds majority. While a resolution of censure was pending Brooks resigned, but was immediately re-elected by his constituents. His action was generally upheld by the Southern leaders and press. The indignation in the North was intense, and the incident crystallized sentiment against slavery more, perhaps, than any other single event had done up to this time.

Sumner was re-elected to the Senate in January 1857, but, owing to the state of his health he spent nearly four years abroad, returning in time to resume his seat in the Senate 5 Dec. 1859. It was not until June 1860, however, that he delivered an important speech on "The Barbarism of Slavery." It was intended as a reply to numerous assertions recently made to the effect that slavery was a moral, social and political blessing, and "enabling to both races, the white and black." The speech was a reservoir of facts drawn largely from Southern sources, and an appeal to the great moral sentiment of the North to help abolish the system.

In the session of Congress which opened 3 Dec. 1860, Sumner devoted himself to preventing any compromise between the slave and the free States; for his object was the destruction of slavery. When the Southern senators withdrew as a result of secession, the committee was reorganized, and Sumner was made chairman of the committee on Foreign Relations. In this capacity he rendered the country signal service during the war. He was largely instrumental in the surrender of the captured Confederate commissioners, Slidell and Mason, who had been taken from the English mail steamer Trent by Captain Wilkes while on the high seas. He showed the President that this would be in accordance with our doctrines and an abandonment of claims made by England to which we had always objected. He used all his influence to prevent foreign intervention, and opposed the use of force in an attempt to get the French troops out of Mexico, as it might result in war. He was opposed to the issuing of letters of marque, and when the bill was passed used every effort to prevent the law going into effect, in which he was successful. His action was that of a friend with foreign nations. His speech in New York, 10 Sept. 1863, was a strong statement of the American position. He raked England for her unfriendly acts with respect to neutrality and for allowing Confederate cruisers to be fitted out in English ports, and called France to account for her intervention in Mexico. The speech had an inpr view upon the French government to bring a check on England. He made an exhaustive report on the French Spoliation Claims. He argued vigorously for the treaty for the purchase of Alaska in 1867. He was in favor of settling all questions of dispute with England and in bringing the two nations into relations of harmony and good will, and hence supported the efforts to settle the Alabama claims. Owing to a disagreement with President Grant and Republican senators over the acquisition of Santo Domingo, which Sumner opposed, he was removed from his chairmanship of the Committee on Foreign Relations, 10 March 1871.

Sumner supported the policy of emancipation and wished to take the step before Lincoln finally acted because he thought that it would prevent foreign intervention. He made the first public demand for emancipation by a responsible statesman on 1 Oct. 1861, before the State Republican Committee of Massachusetts, and repeated his demand in a number of a number of a number of speeches in the next few months. In the session of Congress which met in December 1861, he spoke in favor of legislation to prevent the surrender of fugitive slaves by the Union army, and in favor of the abolition of slavery in the District of Columbia, the first public word on the subject since the Republican party came into power.

During the war and after he was active in furthering the interests of the negro. He was influential in getting ratified the treaty with England for the more effectual suppression of the slave trade. He proposed bills allowing colored persons to become mail carriers, for enlisting negroes freed by Confiscation Act and for receiving colored volunteers. He proposed and carried legislation preventing the exclusion of witnesses in the courts of the District of Columbia on account of color. He voted against the bill to admit West Virginia, because the Senate refused to amend it so that after 4 July 1863 slavery should cease in that State. He was continually urging Lincoln to issue the Emancipation Proclamation. He introduced a bill in the Senate to repeal all fugitive slave laws, and succeeded in getting a similar bill, which had been passed in the House, through the Senate. He began the contest for negro suffrage, was a leader in his effort to prevent the exclusion of colored persons from street cars in the District of Columbia, supported a bill to secure for colored soldiers equal pay with the white and was energetic in getting the bill passed to establish the Freedman's Bureau, which Sumner called "a bridge from slavery to freedom." He also aided in forcing a repeal of the law which excluded colored testimony in the United States courts, and was largely responsible for the admission of a colored man to the bar of the Supreme Court, the privilege being granted by Chief Justice Chase on motion of Sumner. He offered an amendment to one of the reconstruction measures to the effect that "every constitution in the new States shall require the legislature to establish and maintain a system of public schools open to all without distinction of race or color."

On the question of reconstruction, Sumner
felt that the conditions must be faced by Congress and the President together, and hence opposed the policies of Lincoln and Johnson, viz., reconstruction by the executive. He considered this policy unconstititional while the Constitution supported the authority of Congress to declare war, and to keep the peace, and the power of the President to arm the territory, to protect the Union, to suppress insurrection, and to enforce the laws. He called this the policy of a "tyrannical executive," and he was a consistent advocate of States' rights. He held that a federal government could exist in this Union a republican form of government. He voted for the conviction of President Johnson in his impeachment trial.

After his removal as chairman of the Committee on Foreign Affairs, Sumner exerted little influence in the Senate, and occupied his time mainly in pressing civil rights bills for negroes. He supported Horace Greeley for President in the election of 1872, on the ground that he was an "unserving" Republican, that principles must be preferred to party and that Grant was unfaithful to the Constitution and Republican principles.

The character of Sumner and his services to his country were both based on fidelity to great moral ideas. He was sincere, unselfish, simple, kind, conscientious, honest and pure and without envy or personal animosity. He was also energetic, uncompromising, courageous and fearless, and indomitable in his purpose. On the other hand, while not entirely a man of one idea, his intense convictions on slavery often helped to defeat his desires, because of his inability to give sufficient weight to other important interests. He became egotistical, domineering, and was lacking in a sense of humor. Next to Lincoln he undoubtedly did more to win freedom for the colored race than any other man. His other great service was in keeping the country out of war with England and France during the latter part of the period of the Civil War, when such a catastrophe might easily have led to a permanent dissolution of the Union.

Bibliography.—The best short life of Sumner is that by Moorfield Storey ('American Statesmen Series,' Boston 1900). Other biographies are those by Edward Lillie Pierce, 'Memoir and Letters of Charles Sumner' (4 vols., Boston 1877–93); by Anna L. Dawes, 'Charles Sumner' ('Makers of America Series,' New York 1892); by George H. Putnam, 'In America: Biographies of Philadelphia, Copyright, 1909'); by G. H. Grimke, 'Life of Charles Sumner, the Scholar in Politics' (New York 1892). The 'Works' of Sumner were published in 15 volumes, Boston 1874–83. A famous oration on Sumner is that by L. Q. C. Lamar, 27 April 1874. Consult also Shotwell, W. G., 'Life of Charles Sumner' (New York 1910), and Whipple, E. P., 'Recollections of Eminent Man.' Some of Sumner's most famous speeches have been printed separately, viz., 'Report of the War with Mexico,' and 'Speech on the Crime against Kansas' (Directors of Old South Work, Boston); 'Address on War, containing True Grandeur of Nations,' 'War System of Nations', 'Duel between France and Germany' (Boston).

Marcus W. Jerden, Associate Professor of History, University of Chicago.

SUMNER, George Watson, American naval officer: b. Michigan, 31 Dec 1841. He was appointed to the Naval Academy in 1858. In the Civil War he participated in the bombardment of Forts Jackson and Saint Philip; commanded the Massasoit on the James River, and with the Onondaga forced the Confederate ironclads to relinquish the purpose of attacking Grant's transports and base of supplies at City Point, Va. After the war he served in various capacities, was commander of the naval station, Fort Royal, Va. C. (1899–1901); in January 1901 was appointed commandant of the Philadelphia navy yard.

SUMNER, Increase, American statesman: b. Massachusetts, 1746; d. 1799. He was graduated at Harvard College in 1767; admitted to the bar in 1770, and in 1779 was a member of the State Constitutional Convention. He was elected to Congress in 1782, a member of the United States Constitutional Convention in 1789, and in 1797 was elected governor of Massachusetts.

SUMNER, Samuel Storrow, American military officer: b. Pennsylvania, 6 Feb. 1842. He was appointed to the army from New York in 1861, served in the Civil War, and against the Indians in the campaigns from 1869 to 1878. In May 1898 he was appointed a brigadie general of volunteers under the command of General Miles, and when American War was assigned to duty in Cuba. He was ordered to England as military attaché, but left there in 1900 to join the United States troops in China. Later he was sent to the Philippines, where he was promoted brigadier general United States army in 1901, and major general, August 1903. His last service was in command of the Division of the Pacific, and he retired 6 Feb. 1906.

SUMNER, William Graham, American educator: b. Paterson, N. J., 30 Oct. 1840; d. 12 April 1910. He was graduated at Yale in 1863, studied abroad, was tutor at Yale in 1866–69, in 1867 took orders in the Protestant Episcopal Church, was assistant at Calvary Church, New York, and rector of church of the Redeemer, Massillon, N. J., appointed professor of political economy and social science at Yale College in 1872. His writings include a translation of Lange's 'Commentary on Second Kings' (1872); 'History of American Currency' (1874); 'Life and Andrew Jackson' (in 'American Statesmen Series' 1882); 'What Social Classes Owe to Each Other' (1883); 'Problems in Political Economy' (1884); 'Protectionism' (1885); 'History of Banking in the United States' (1896); 'Robert Morris' (1892).

SUMPTUARY LAWS, a term often used in American political discussion with reference to laws regulating the sale of liquor. The original meaning, however, was the regulation by law of eating and drinking, wearing apparel and style of living generally. The early settlers of New England adopted harsh laws of this character, which have been exaggerated and caricatured in the fictitious Connecticut *Blue Laws* of the Rev. Samuel A. Peters. Sumptuary laws existed in ancient as well as modern times. One such law or the Twelve Tables aimed at repressing extravagance in funerals. After the establishment of the censorship holding this office had the right of punishing those guilty of luxurious living. After the Twelve Tables the first sumptuary law passed at Rome was the Lex Oppia (215 B.C.), directed exclusively against the ex-
SUMTER—SUN

travagance of women in dress, jewelry, etc. This law was repealed 20 years later. The other sumptuary laws enacted at Rome were almost exclusively designed to keep down extravagance in entertainments. The *De Julia*, passed in the reign of Augustus, was the last sumptuary law passed at Rome, but a few endeavors were made under later emperors also to repress luxury by decrees of the Senate and imperial edicts. The last attempt of this nature that have been made belongs to the reign of Nero. Sumptuary laws were revived by Charlemagne. Both he and Louis the Debonnaire promulgated capitularies against luxury in dress and furniture. Various other laws and decrees having a like object were made under many of the later kings of France, even down to Louis XV. A royal ordinance, dated 19 April 1737, forbids the common people (*tulains*) the use of calico, which was reserved for the nobility, and there are instances of the wives and children of commoners being fined in virtue of this decree. In England sumptuary laws began to be enacted in the reign of Edward III, and continued to be passed down to the time of the Reformation. Most of them were repealed by 1640, but their use was not all expunged from the statute-book till 1856. Sumptuary laws in the early colonial period of America were not confined to New England. Directions were sent to Virginia in 1621 not to permit even the members of the council to wear gold in their clothes, or to wear silk till they make it themselves. In New England the Massachusetts magistrates prohibited the wearing of gold, silver or thread lace, all embroidery or needlework in the form of caps, bands or ruffles, gold and silver girdles, and other extravagances which offended Puritan simplicity. The laws were, however, ignored or but slightly enforced, and gradually became obsolete. At present in the United States dress is solely a question of decency, and sumptuary laws are, in that sense, of the past.

SUMTER, Thomas, American military officer: b. Virginia, 1734; d. 1 June 1832. After the capture of Charleston by the British in 1780 he took the field as a brigadier-general and on the 14th of May, 1781, he was one of the most active and able partisan leaders of the South. His bravery, endurance and unvarying cheerfulness and determination under reverses gained him from his followers the sobriquet of the Carolina game cock, and Cornwallis confessed that he was one of his greatest plagues. After gaining important successes over the British and Tories, he was, in September 1780, routed with considerable loss near the mouth of Fishing Creek on the Tarawa by Tarleton. In 1781 he took a distinguished part in the battle of Eutaw Springs. The thanks of Congress were tendered him in 1791, and he was afterward sent to that body as a representative of South Carolina. In 1809 he was appointed United States Minister to Brazil and two years later was elected United States senator.

SUMTER, S. C, city, county-seat of Sumter County, on the main line and several branches of the Atlantic Coast Line Railroad, 90 miles north of Charleston, is an agricultural region producing cotton, tobacco and vegetables, of which it exports large quantities. It also has manufacturing interests of importance which include cotton factories, planing mills, sash and blind factories, etc. There is a national bank and a State bank. The city has a public high school founded in 1889, and is the seat of Saint Joseph's Academy, a Roman Catholic school for girls, and of the Sumter Military Academy and Female Seminary, a coeducational non-sectarian school. Since 1913 the commission form of government administers city affairs. Pop. about 9,400.

SUMTER, Fort. See Fort Sumter.

SUMY, soo'më, Russia, a town in the government of Kharkov, on the river Psel, 81 miles north of the town of Kharkov. It has nine churches, a gymnasium, technical school, banks and a large sugar refinery, besides numerous distilleries. The soil is productive, and agricultural products are exported together with brandy. Four annual fairs give considerable impulse to trade. Pop. 51,500.

SUN, the great central body of the solar system. The aspect of the sun with which all are familiar from infancy shows that it is a shining globe. Astronomical measurements show that this globe is more than 140 times the diameter of the earth, and, therefore, more than 1,000,000 times its volume. Its small apparent diameter is due to its enormous distance of 93,000,000 miles. The following are more exact numerical particulars:

<table>
<thead>
<tr>

For methods of determining the distance and other quantities see ASTRONOMY, Theoretical.

The aim of the present article is to set forth the physical constitution of the sun, so far as modern research has made it known.

One of the most certain results of research is that the sun is at an extremely high temperature, higher than any that we can produce in our furnaces. This is shown by two considerations. One is the enormous amount of energy radiated, which suffices to support life on its surface, notwithstanding the immense distance at which it is placed. Nothing but a hot body could radiate so great a volume of energy. Another proof of the high temperature is shown by the spectroscopic, which discloses the vapor of iron and other refractory metals in the sun's atmosphere. It requires a hot furnace to melt iron. Much higher must be the temperature which would make it boil away like water. The temperature of the sun not only does this, but the fact that the spectral lines of iron are dark on a bright ground shows that the solar light emanates from a body yet hotter than the vapor of iron.

Aspect of the Sun.—We can see only the surface of the sun, not its vast interior. To distinguish the two, the shining region is called the *photosphere*. The latter presents to our view the appearance of a flat disc. The edge of this disc is called the *limb*. When seen without telescopic magnification, through a dark glass or other medium, the edge of the sun appears quite uniform, slightly shaded off at the limb. But when carefully examined with
the telescope, under good atmospheric conditions, the entire photosphere appears as a darkish background, sprinkled with brighter grains or nodules. These "rice-grains" are quite irregular in size and form, and appear as if bright on a relatively dark or yellowish background. It is probable that they are produced by currents of heated matter from the interior, hereafter to be described, which are constantly rising to the surface, there to radiate their heat and then fall back again. When the intensity of the heat radiated from different parts of the photosphere is accurately measured, it is found that the amount of radiation diminishes from the centre of the disc to the limb, where it is least. The diminution is slow at first, but increases quite rapidly at the limb, where it is little more than one-half of that at the centre. The light diminishes in a still greater ratio than the heat. The tint of the light is also different.

at the centre and at the limb, although this would hardly be noticed by the eye. The light at the limb has more red in its composition than at the centre. This effect is especially noticeable at the time of a total or annular eclipse of the sun. When the moon has nearly covered the sun, the remaining light has a lurid aspect, as if the sun were shining through a smoky atmosphere, thus giving to observers the illusion that the sky is hazy. There can be no doubt of the cause of this appearance. The sun, like the earth, is surrounded by an atmosphere; but this atmosphere is cooler than the photosphere which sends out the light and heat. The existence of the atmosphere is demonstrated by the lines of the spectrum, as well as by the absorption of heat at the limb, which is greater than near the centre because the light coming from that portion of the photosphere has to pass through a greater depth of the atmosphere than when it rises directly upward from the centre.

The Solar Spots.—When the Galilean telescope was first pointed at the sun, the observers were surprised to find that that object was now and then variegated by dark spots. These were observed by Galileo, Scheiner and Fabricius. The two latter published more or less elaborate treatises on the subject, but with their imperfect instruments they were not able to learn much as to the laws of these objects. We now know, with the modern perfected methods of observation, that the spots are of very different sizes, ranging from the minutest point visible in the telescope to a size so great as to be perceptible to the naked eye. The largest must, therefore, exceed the earth itself in diameter. These objects are usually very irregular in their outline, being frequently jagged and cornered, as if made by a shot or bunch of shot passing through a tin plate or wooden plank. They frequently appear in groups; indeed a spot visible to the naked eye commonly consists of a group of these objects close together. The spots of the group may run into each other to any extent, forming an irregular and jagged mass. Sometimes a spot has almost the appearance of a crack in the photosphere. In the spot two portions can generally be distinguished, a dark interior called the "umbra" and a shaded border, much brighter than the umbra, though not quite so bright as the photosphere, called the "penumbra." When the atmosphere is steady, the latter is seen, with a good telescope, to be not of uniform shade, but to be striated, presenting an appearance somewhat like that of a thatched roof. This can be seen better by a figure than by a long description. A spot seems black only by contrast with the brilliancy of the sun. If it were possible to cut off the sun's light, the light from the spot itself would be of dazzling brightness.

It was formerly supposed that the spots were openings in the photosphere, through which a darker interior was seen. This conclusion was reached because it was supposed that when
the spot approached the edge of the solar disc
the penumbra looked broader on the side of the spot
next to the edge. But careful observations
made in recent times show that this is not the
case, as great as the penumbra is broader at
one edge and sometimes at another. It was also
supposed that the spots might be something
in the nature of cooler dark metals floating on
the photosphere. But this view also has been
abandoned. It has recently been shown by Nic.
the sun spot as an enormous flux of ions which
whirling electrically charged particles produce
an intense magnetic field. Thus a sun spot
resembles a terrestrial tornado. The observations
of Evershed and St. John indicate that the
gases are rising from the interior of the sun
toward the surface, flowing nearly radially out
above the surface from the centre of the
spot. Measurements of the heat radiated from
the spot, as compared with that of the neighboring
disc, show that the spot is really cooler than
the rest of the photosphere. Spectroscopic ob-
servations agree with this by showing a great
absorption of the light coming from the interior
of a spot.

Another salient feature of the sun is its
rotation on an axis deviating only six degrees
from a line perpendicular to the ecliptic. The
time of rotation is shown by observations of
the spots on the sun, which we see to move
from east toward west. The relation of the
sun to its own axis of rotation is much the same
as in the case of the earth. The sun's axis inter-
sects the photosphere at two opposite points
called the poles of the sun. A circle passing
round the sun midway between the poles is
called the solar equator. Distances north and
south of the equator are called solar latitude.
When we look at the sun at noon its north and
south poles are near the upper and lower points
of the disc; and the equator passes horizontally,
or nearly so, across the centre of the disc. The
position of the sun's equator is more exactly
defined by the following numbers:

<table>
<thead>
<tr>
<th>Inclination to the ecliptic</th>
<th>7° 15'</th>
</tr>
</thead>
<tbody>
<tr>
<td>Longitude of the node</td>
<td>74° 29'</td>
</tr>
</tbody>
</table>

The earth in its annual course around the
sun passes through the line of the nodes about
3 June and 3 December of each year. At these
times the apparent paths of the spots across the
sun's disc are straight lines. At the interme-
ciate times they are more or less curved. In
March the south pole is slightly turned toward
us, and the paths of the spots are curved up-
ward. In September the reverse is the case.
We see only the north pole, and the paths are
curved downward.

Observations of the spots lead to the unex-
pected conclusion that the equatorial regions
of the sun rotate in less time than those nearer
the poles, although the distance they have to go
is greater. The sun is so much larger than the
earth that, although the time of rotation is more
than 25 times as long, yet the absolute linear
velocity of the rotation near the equator is four
times as great as that of the earth's rotation,
being very nearly one mile per second.

The observations of Carrington give the
period of rotation as follows:

| At the sun's equator | 24.9 days |
| At 30° of latitude   | 26.4 days |

The apparent time of rotation, as we see it,
is nearly two days longer, because the earth
has carried us forward in its annual motion
while the sun is rotating, and the spot has to
catch up to our direction before a rotation seems
complete.

The rotation of the sun can also be de-
termined by means of the spectroscope, through
this instrument enabling us to determine
whether a luminous body is approaching the
earth, or receding from it. In consequence of
the rotation, the photosphere on the east side
of the sun is continually moving toward us, and
that on the opposite side moving away from us.
The observations made by this method agree
with those made on the solar spots in giving a
period of about 25 or 26 days; but they are discordant
as to the variation with latitude. The angular motions in the different latitudes, found
by two observers with the spectroscope, Duner
and Adams, are as follows:

<table>
<thead>
<tr>
<th>Latitude</th>
<th>Spots (Carrington)</th>
<th>Spectroscopic</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>14.6°</td>
<td>14.6°</td>
</tr>
<tr>
<td>11</td>
<td>14.9</td>
<td>14.3</td>
</tr>
<tr>
<td>15</td>
<td>14.12</td>
<td>14.28</td>
</tr>
<tr>
<td>21</td>
<td>13.90</td>
<td>13.76</td>
</tr>
<tr>
<td>30</td>
<td>13.65</td>
<td>13.64</td>
</tr>
<tr>
<td>45</td>
<td>13.10</td>

<td>11.99</td>
<td>12.78</td>
</tr>
<tr>
<td>75</td>
<td>9.34</td>
<td>10.86</td>
</tr>
</tbody>
</table>

It is a remarkable and interesting fact that
the velocities thus determined by the displace-
ment of spectral lines differ systematically when
the lines of different elements are chosen. Thus,
the values determined by Adams from the lines
of iron, calcium and hydrogen, are as follows:

<table>
<thead>
<tr>
<th>Solar Latitude</th>
<th>Iron lines</th>
<th>Calcium lines</th>
<th>Hydrogen lines</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.3°</td>
<td>14.65°</td>
<td>15.0°</td>
<td>15.2°</td>
</tr>
<tr>
<td>14.9</td>
<td>14.31</td>
<td>14.9</td>
<td>15.0</td>
</tr>
<tr>
<td>29.7</td>
<td>13.65</td>
<td>14.7</td>
<td>14.6</td>
</tr>
<tr>
<td>44.7</td>
<td>12.85</td>
<td>13.6</td>
<td>14.0</td>
</tr>
<tr>
<td>60.0</td>
<td>11.93</td>
<td>13.1</td>
<td>14.3</td>
</tr>
</tbody>
</table>

This difference agrees with much other evi-
dence on the same point in indicating that the
different elements effective in producing the
lines lie at different levels around the ball of
the sun.

The rotation of the sun must produce an
eLLipticity or bulging out of the equator, as in
the case of the earth. But this effect is so small
as to elude all astronomical measurement.
To all appearance the sun, notwithstanding its
rotation, is a perfect sphere.

Two very remarkable laws govern the solar
spots, one relating to their frequency, the other
to the region of the sun's disc on which they
are seen. We recall the fact of the sun having
north and south latitude as we have on the earth. The first peculiarity of the spots is that they are rarely seen at more than 35° to 40° of solar latitude, north or south. They are most numerous at about 15° latitude, and from that parallel grow less numerous both toward and from the equator. At the equator they are comparatively scarce. Thus we see that there are two zones of spots; one north and the other south of the sun's equator. The following table of the number of spots observed by Carrington in different zones of latitude illustrates the law:

<table>
<thead>
<tr>
<th>Limiting lat. of zones</th>
<th>Number of spots</th>
</tr>
</thead>
<tbody>
<tr>
<td>0° to 5°</td>
<td>471</td>

<td>2,158</td>
</tr>
<tr>
<td>20 to 25°</td>
<td>1,083</td>
</tr>
<tr>
<td>25 to 30°</td>
<td>740</td>
</tr>
<tr>
<td>30 to 35°</td>
<td>303</td>
</tr>
<tr>
<td>35 to 40°</td>
<td>84</td>
</tr>
</tbody>
</table>

The other remarkable feature of the spots is their periodicity. At intervals of 11 years they are very numerous, while at the intermediate times they are comparatively scarce, never being with the facts half the time. It is found that the period is almost exactly 11 years 47 days. It was at one time supposed to be the same as the period of revolution of Jupiter, which is somewhat less than 12 years. Had such been the case we should have concluded that the spots were in some way produced by the action of that planet. But it is now proved that the period is more than six months less than that of Jupiter, and does not coincide with any other period known in the solar system. Its average duration is found to be 11.13 years; but it is subject to changes of a year or more. We, therefore, conclude that the cycle of change in the spots is due to a round of processes going on inside the sun itself. What these may be we have no means of determining.

The very careful series of photographs of the sun made at the Greenwich Observatory during the past 30 years show a singular law of variation in the spots with the 11-year period. After a space of two or three years, during which, as we have said, the spots are few and small, the first evidence of a renewal of activity is seen in the occasional appearance of a spot at an unusually high latitude, say 30° to 35° north or south. This may continue for several months, or even a year. Then the spots begin to be more frequent nearer and nearer the equator, while there are fewer beyond 30° of latitude. Finally, after three or four years, they become thickest of all, as we have said; in about 15° of latitude. About five years from the time when fewest are seen, they will be most numerous; then they will also be seen nearer the equator or even on the equator itself. After five years they begin to diminish rather more slowly than they increased, until they gradually seem once more almost to disappear. The years of minimum sun spots are 1839, 1900, 1911, etc. The years when they are most numerous were 1882, 1893, 1904, etc. But these dates are only approximate, as the intervals between the minima are not always exactly the same.

The Faculae.—Another curious feature of the sun is the occasional appearance of spots brighter than the rest of the photosphere. These commonly appear in bunches in the neighborhood of the spots, and derive their name from the Latin word facula, a torch. They follow a law similar to that of the spots not only in having the same period, but also in being most numerous where the spots are most numerous. But they are seen over a very much wider region of the sun's disc than the spots, sometimes, although rarely, near the poles of the sun.

A third feature of the sun associated with the spots and the faculae is known as the "prominences." These can be actually seen through an ordinary telescope only during total eclipses of the sun. But they may now be seen at any time, when the air is clear, by means of a powerful spectroheliograph. Like the faculae, they are commonly, but not always, found in the neighborhood of the spots, being seen from time to time all round the sun's limb. (See Eclipse.) They will be described more fully hereafter.

It is quite evident, from what we have said, that the spots, faculae and prominences are all results of one series of operations. This fact has been being verified by the spectrophotograph and especially by the spectroheliograph. This is an instrument invented by George E. Hale of the Mount Wilson Observatory, which enables a photograph of the sun to be taken by the light of a selected ray of the spectrum, and excludes all the other rays being cut off. A ray frequently used for the purpose is one emitted by calcium. When a photograph is taken with this ray, we have not a general photograph of the sun by its light, which is what the ordinary camera would give us, but a photograph in which no light is allowed to enter except that emitted by the vapor of calcium. A photograph thus taken is found to be extremely variegated, some parts of the sun's disc being much brighter than others. The interesting feature is that, in the general average, the brightest parts of the disc are those where the spots, faculae, and prominences are most numerous. But these bright patches may appear on any part of the sun. The general conclusion is that all the objects we have described are all produced by processes going on in the sun which result in the throwing up of great masses of calcium vapor. Having thus described what the sun is in a general way, and shown its appearances, we pass on to particulars respecting its constitution and surroundings. Our conclusions must be drawn step by step from the phenomena exhibited by the photosphere, combined with reasoning upon the laws of force and the properties of matter. A conclusion most easily reached is that the sun is not a solid body throughout. If it were, its enormous radiation of heat would result in the surface rapidly cooling off, so that, in a very short time, it would cease to emit light. Moreover, a study of the surface shows changes constantly going on incompatible with the idea of solidity. It follows that the heat radiated from the surface must be continually being supplied either by the rising up of hot material from the interior, or by radiation from within outward. It is the latter which is believed to be acting. For the material of the sun is probably transparent, and it is supposed that the enormous heat is absorbed and re-radiated as we pass outward from the center.

2. The corona of the sun during the total eclipse of 28 May 1900.
3. Calcium flocculi in the neighborhood of a sun-spot. Photographed with the spectro-heliograph, 19 October 1903, at the Yerkes Observatory.
1 The appearance of the corona during the total eclipse of 30 August 1905
2 Spectro-heliogram of the whole disk of the sun taken at the Yerkes Observatory, 12 August 1905
The absorption and re-radiation from successive layers is almost instantaneous, the velocity of transference approaching 180,000 miles a second.

In drawing our conclusions the intensity of gravitation on the sun must be borne in mind. It has nearly 28 times the force of gravity on the earth. A man of ordinary size would weigh two tons at the surface of the sun, and would, therefore, be instantly crushed to death by his own weight, were it possible for him otherwise to exist there. Consequently, the pressure to which the vapors of the sun are subject increases with enormous rapidity below the surface.

The average specific gravity of the materials composing the sun can be determined by astronomical theory with great exactness. It is known that the mean specific gravity is about 40 per cent greater than that of water, and one-quarter of that of the earth. It is doubtless much smaller than this at the surface, and, therefore, increases toward the centre. A calculation of the resulting pressure shows that near the centre the sun is produced by the enormous mass and gravitation of the matter composing the solar orb amounts to about 5,000,000 tons per square inch. This pressure is so far beyond any that we can produce at the earth's surface that we are unable to say what effect it would have upon matter.

Yet another unknown factor is the temperature of the interior. At no great distance toward the centre the temperature exceeds the powers of determination—it may even be 1,000,000°. As the highest temperature which it is possible to produce artificially probably does not amount to 12,000°, it is impossible to say what effect such a temperature would have upon matter. Thus we have two opposing causes: the one an inconceivable degree of heat, such that, were matter exposed to it on the surface of the earth, it would explode with a power to which nothing within our experience can be compared, and a pressure exceeding thousands of times any we can produce, tending to condense and solidify this intensely heated matter.

One thing which we can say with confidence as to the effect of these causes is that no chemical combinations can take place in matter so circumstanced. The distinction between liquid and gaseous matter is lost under such conditions. Whether the central portions are compressed into a solid, or remain liquid, it is impossible to say.

Modern research shows that the sun, as a whole, is a complex body, the various parts of which are in very different conditions. Beginning at the centre and passing outward, we have first the vast, invisible interior which forms the globe itself, and which our sight can never penetrate. Surrounding this interior is the visible photosphere, or seeming surface, which we see with the naked eye or the telescope, the appearance of which has been fully described. So far as necessary direct observation could show, this would be the whole of the sun when the sun is beyond the red envelope which hides the real sun to us at the earth, the darkness of the great night of the sun. But what we see is a bright envelope which hides a real sun the brightness of which we never see.

The earliest accurate observers of total eclipses with the telescope noticed that during the total phase red cloud-like masses were seen here and there projecting beyond the limb of the dark moon. Moreover, at the beginning or the end of the eclipse, it is found that these projections are connected with a red border extending round the sun. There is, therefore, an envelope which hides a real sun behind the red cloud-like masses which are seen and is invisible except during eclipses. Quite independent of this envelope is a bright effulgence which is seen during a total eclipse. These phenomena are fully described in the article Eclipse. The phenomena observed during the eclipse of July 22, 1878, are described in the article Eclipse.

The red envelope which rests immediately on the photosphere is called the "chromosphere." It is comparatively thin—so thin as to be almost immediately covered when the sun is totally eclipsed. Its nature was first made known by the spectroscope, which showed it to be composed mostly of hydrogen, helium, and calcium vapor. Its principal and lower parts differ in constitution. At the photosphere it comprises nearly all the substances which exist in the latter. This was shown in a very beautiful way by observations of the reversing layer, first made by Young at the total eclipse of 1870. The explanation of the phenomena there described is that the photosphere is hot enough to shine by its own light, and, being a gas, to give bright spectral lines. But the photosphere is so much hotter than the chromosphere that the latter is, in comparison, a cool gas which absorbs the spectral lines from the light radiated by the photosphere. The question of the density of the chromosphere and reversing layer, as its base is called, has given rise to very varied estimates.

The fact that the spectroscope shows bright lines as the last ray of true sunlight disappears at the beginning of a total eclipse shows that the gas from which these lines emanate must be so rare as to be transparent through a distance of thousands of miles. We are, therefore, justified in concluding that the gases of the chromosphere are extremely rare, and the same is probably true of the principal regions of the photosphere.

Among the most extraordinary phenomena exhibited by the sun are the mountainous elevations of the chromosphere, which we see as the red protuberances already described. These are of two kinds, the eruptive and the cloud-like. The latter present to us the appearance of vast clouds floating in an atmosphere of the sun. It seems certain, however, that they cannot be what they seem, because there can be no atmosphere there to support them. They are probably held up by an impulsion of the solar rays, which will be described presently. The eruptive prominences seem to be due to outbursts of intensely hot gases, mostly hydrogen, from the sun. These are thrown up with a velocity of several hundred miles per second, like immense mountains of fire. They sometimes rise to a height of many thousand miles, their ascent being doubtless aided by the impulsion of the solar rays; then they fall back again to the sun. The chromosphere and prominences can now be photographed in projection against the sun's disc with the spectrophotograph. When such photographs are made with the light of the red hy-
hydrogen line, they show great vortex phenomena, centering in sun spots and closely related to the vortices in the photosphere which constitute the spots themselves. See Plate III.

The violent forces seen in action in the chromosphere are in singular contrast to the soft white light of the corona. Much mystery still surrounds the constitution of the latter. It was supposed to be an atmosphere of the sun; but this view is rendered untenable by the fact that an atmosphere supported by its own weight would more than double in density for every mile, that it was nearer its base. It probably consists of exceedingly minute molecules of gaseous matter, similar to those which make up the tail of a comet, and possibly having some resemblance to the latter. The newly-discover-

Prior to 1905 the true value of the constant was in much doubt; numbers ranging from 1.76 to 4.19 were stated for it; and the average value 3.0 was frequently accepted. There can be no doubt that the value 1.95 is very near the truth, and this may be regarded as the best value now obtainable. It has been well established, however, especially by the recent work of Abbot, that this fundamental constant varies slightly and irregularly. In 1919 a solar station was established at Calama, Chile, at which it is planned to make constant measures of the sun's radiation for several years, in conjunction with observations, with a special view of ascertaining, if possible, the law of this variation, and its effects upon terrestrial climates.

The Sun's Magnetism.—In the year 1908, Prof. G. E. Hale of the Mount Wilson Observatory, from an examination of the spectral lines in sun spots, discovered that around each spot there is a more or less powerful magnetic field. A powerful field will double many of the lines of the spectrum; a less powerful one will widen them. A few lines were found triple in sun spots, and afterward these same lines were found to become triple in the laboratory when viewed along the magnetic lines of force. Thus the lines of sun spots near the sun's limb tend to become triple, while those from spots near the centre of the solar disc are doubled merely. In many cases a pair of sun spots quite near together are found to have opposite polarity, and while in general the polarity of spots in the southern hemisphere is different from that in the northern, many cases of exception occur. It has, however, been well established that the sun, like the earth, has a north and south magnetic pole; the inclination of the sun's magnetic axis has been determined, and the fact has been established that the magnetic pole is in slow rotation about the pole of the sun.

A curious relation is found by the study of magnetic storms on the earth. The latter consist in occasional perturbations of the magnetic needle, which are very irregular in their character and are felt over the whole globe. They
1 Solar prominence 80,000 miles high, photographed with the spectroheliograph on Mount Wilson
2 The chromosphere and prominences photographed in projection against the sun's disk, showing the hydrogen
vertices centering in sun-spots discovered at Mount Wilson
generally occur when there is an unusually bright aurora. Now, investigations show that the number of these disturbances follows exactly the period of the solar spots. During those years when the spots are most numerous magnetic storms are most frequent, and vice versa. The conclusion is that the sun spots and magnetic storms are due to the same cause. The sun’s spots can be due only to something going on in the sun, and it follows that there must be some emanations from the sun which produce magnetic storms. Modern investigations have not been able to detect or define these emanations, though they are supposed to be electrically charged particles, shot out from the sun, and drawn in around the magnetic poles of the earth, where they give rise to the aurora.

We have the strongest reasons to believe that neither the magnetic field of the sun as a whole nor the much more intense local fields in sun spots, produce any measurable magnetic effect at a distance of the earth.

Age and Duration of the Sun.—The greatest problem connected with the sun is suggested by modern science. Up to 100 years ago students and philosophers saw no reason why the sun should not continue to shed heat and light on the earth for an indefinite period without undergoing any change whatever. But toward the middle of the 19th century the laws of energy were developed and understood. These laws set forth that the radiation of heat always involves the expenditure of something called energy, and that the latter is necessarily limited in supply. It was also seen that the sun must be a hot body, and must lose all the heat it radiated. To make this subject clear, we must remark that what the sun really radiates is not properly called heat in scientific nomenclature; the more exact term is radiant energy. But this differs in no respect from what is radiated into a room from a hot fire. Radiant energy goes out from the fire and strikes the walls of the room, where it creates heat, and thus warms the walls. All the heat thus transmitted to the walls comes from the coal, although in its passage from the fire to the walls it passes through an intermediate stage called radiant energy. That the latter depends on the temperature of the body from which it is passed is shown by the striking experiment of making a large lens out of ice instead of glass. When the sun’s rays are concentrated on a point by passing through this mass of ice they will burn the substance on which they fall, as if they had passed through glass. We see, then, that however cold the space between us and the sun may be, all the radiant energy reaching us from the sun must come from a source in the sun limited in accordance of the earth.

If the sun were merely losing energy like an ordinary hot body cooling off, a very simple calculation will show that it would be so cooled off in the course of 3,000 or 4,000 years as no longer to radiate much heat. It is clear that such has not been the case. Yet the most careful study shows no possibility that it can be receiving any considerable part of its energy from any outside source. Moreover, the geologists assure us that the stratification of the rocks, and planets, in ancient phenomena associated with them, proves that the sun has been radiating heat to the earth at not much less than its present rate for hundreds of millions of years.

The only solution of the puzzle that was suggested until 1903 was based on the mutual convertibility of heat and motion. From the time that the theory of energy was developed it was known that when the motion of a material substance is arrested without any other effect being produced, heat is generated. For example, the waters of Niagara are warmed by about one-quarter of a degree Fahrenheit in striking the bottom of the falls. The blacksmith by hammering a piece of cold iron can make it hot, because the energy which he puts into the motion of the hammer is converted into heat when the latter strikes the iron. It follows that if bodies of any sort are falling into the sun, heat will be generated by the fall. Moreover, owing to the power of the sun’s attraction, such bodies may fall with great velocity; and the heat thus generated increases as the square of the velocity. Thus arose the first theory as to how the sun’s heat could be kept up. It was supposed that meteors were continually falling into that luminous, but further study showed it to be impossible that meteors could fall in such quantity as to have this effect.

Then it was suggested by Helmholtz and Thomson that if the sun were a gaseous body, as it is now supposed to be, radiating energy, the loss of the latter would continually be made up by the fall of its outer portions involved in the continual contraction of the sun through loss of heat. All bodies, and gaseous ones in a higher degree than any others, diminish in volume when they cool off. Accordingly, when the photosphere of the sun cools off, it diminishes in volume, grows smaller and falls down upon the mass of the sun below it. Careful calculation shows that if the sun contracted about 250 feet per annum, the energy thus generated would keep up all the heat which the sun radiates. An important addition to this theory was made by J. Homer Lane, who showed that if the sun contracted like a mass of pure gas it would continually grow hotter as it contracted. This is now known as Lane’s law. But there is a necessary limit to the quantity of heat which can thus be generated. If the sun has been thus growing smaller through long ages, there must have been a time when it filled the whole space now occupied by the solar system. What is more, the contraction must have been far more rapid the larger the sun was; because the force of attraction at the sun’s surface diminishes as the inverse square of the diameter of the sun. For example, when the sun was twice as large as it is now, this force was only one-quarter as great; consequently it would have to contract four times as much to generate a given amount of energy as it does now. Finally, exact computation showed that even on this theory there was still a limit to the existence of the sun too narrow to satisfy the demands of geology. It could not have been radiating heat for more than 50,000,000 or 100,000,000 years. Before that time it must, according to the theory, have been a gaseous mass filling the whole space now occupied by the solar system, which contracted and formed sun and planets, in accordance with the theory known as the *nebular hypothesis.*

It also seemed very improbable that the sun's
heat could have been at all constant for even
20,000,000 years; on the other hand, geologists
went hundreds of millions of years. Thus ap-
parently an irreconcilable contradiction was
presented to scientific investigators when in 1900
the discovery of radium began to put a new
face upon the fundamental theories of physical
science. We now know that there is an in-
mense amount of energy stored in the atom,
which is a very complex thing. With the so-
called *radioactive* substances, the atoms may
be broken up, the result of the process being an
element of lower atomic weight than the original
substance. And in this breaking up of the atom
a great amount of energy is liberated. Though
it has been known for many years that Helm-
holtz' theory was inadequate, whether a large
part of the sun's energy is of this sub-atomic
origin, we do not know, but it is reasonable to
suppose that it is. And it is only necessary to
suppose that a part of the energy of the atom
is in this way changed into heat energy to al-
most indefinitely prolong the life of the sun.

The most recent semi-popular but authen-
tic work is *The Sun* by C. G. Abbot (New
York 1911); this contains many references to
more extended works or detailed publications.
A larger and very important work is *Physik
der Sonne* by F. Poggendorf (Leipzig 1916).
Numerous papers will be found in the Proceed-
ings of the Royal Society, London, and in the

AND DECORATIONS.

**SUN-BIRDS,** a large family (*Nectariniidae*)
of small insect-eating birds of the tropics of
the Old World, having elongated, slender and
wings of moderate size and the central tail-feathers usually prolonged beyond
the others. These birds occur in the Eastern
Archipelago, India and Africa. They take the
place of the humming-birds of the New World,
and in brilliant colors and habits much resemble these, but are far removed from them
in classification, the honey-eaters (*Meliphagi-
da*) being their nearest relatives. They are
constantly hovering about flowers seeking the
minute insects found within the petals and sip-
going the flower-juices, so that they have been
named suncreters or sugar-eaters, by French au-
thors. Some certainly eat fruits. The song is
sweet, but without any special characteristics, and in habits they are exceedingly lively, quar-
relsome and even pugnacious. The gaudy
plumage is chiefly confined to the male sun-
birds and depends for effect upon intensity of
color and not upon metallic or prismatic lustre.
The nests are built in the hollows of trees or
are placed in thick bushes. Some species (such
as *Nectarina lotenia* and *N. asiatica*) make
dome-like nests, which are suspended from the
extremities of twigs of bushes, and are covered
with cobwebs for the purpose of concealment.
As magnificent treatise upon these birds, while
colored plates, has been written by Shelley, en-
titled *A Monograph of the Nectariniidae*;
(London 1876-80). The name is sometimes
given to various other birds. Thus the sugar-
birds or banana-birds (qq.v.) of the West
Indies are often so called; and a large South
American bird, also called finfoot, for which
see HELIORNITHIDAE.

**SUN-BITTERN,** an extraordinary somewhat-rail-like bird of Brazil and Guiana (*Erythropilus*). It is about 16 inches long, body small and thin, neck long and slender, head like that of a heron, with a long, powerful
beak compressed at the sides and slightly
arched at the culmen; the plumage is mostly
variegated with bars and spots of many colors,
and it has the habit of spreading wings and
tail in courtship or on other occasions of ex-
citement, forming a rosette about its head and
neck fancifully compared to a "sunburst." It
is often made a pet by the Brazilians, who call
it peacock. A larger species (*E. major*) in-
habits Venezuela and Colombia. Their nearest
relative is the kagu (q.v.). Consult Newton,

**SUN CRACKS.** See Mud CRACKS.

**SUN-DANCE,** a ceremony performed, with
local variations, by authentic tribes including
the Mandan, Omaha, Pawnee Loup, Cheyenne, Arikara, Hidatsa, Blackfeet, Nez
Percé, Winnebago, Yankton, Santee and Kiowa.
It is held apparently at the full moon occurr-
ing at or next after the summer solstice, and
lasts from three to six days. The dance of the
wild sage also indicates the times for hold-
ing the ceremony, and all neighboring tribes,
whether friendly or not, are usually invited.
The dance begins at sunrise and ceases at the
following sunrise. As may be inferred from
the length of the festival, including the fasting
and purification of the devotees and other
preparatory acts, the actual sun-dance is
but the chief episode in a ritual comprising a
congeries of ceremonies. The motive or pur-
pose of the dance is to promote welfare through
the gratification of desires and wants and to
avoid ill-fare through the dispensing of hostile
agents. The devotee or sun-dancer indulges in
the ceremony to fulfill a vow, made by him
during the previous winter or season from vari-
ous motives, that he would make a prayer to the
dispenser of what he needs through an ap-
pel to the sun, to *Wakanda* (among the
Sioux). The Tetons call the ceremony by a
name which means *They dance looking at the
sun.* In it the moon is regarded as the repre-
sentative of the sun, hence the dancers gaze
at it just as they do at the sun. Among
the principal objects in the festival of the sun-
dance is the sun-pole or "mystery tree" (sym-
bol of the centre of the four quarters of the
heavens), the sacred tent of preparation erected
within the so-called camping-circle of the tribe,
wild sage, a sweet-smelling grass called *wach-
ogya* by the Tetons and the dancing-lodge.
Each devotee persists in having received a vision from the sun; but if at the
close of the ceremony no such vision has been
voiced, his resort is had to self-sacri-
ifice, which is called *vision-hunting.* One of
the characteristic forms of self-sacrifice is that
of having two wooden skewers inserted under-
neath strips of skin raised by slashing the
breast or back, to which stout thongs are made
fast, by which the devotee is drawn up and
fastened to the sun-pole, to which he remains
suspended until his weight, sometimes made
greater by having a buffalo-skull hung to his perambulated center to rend the skin, thus letting the devotee fall to the ground, usually in a faint; another may have a buffalo-skull suspended from thongs passing through raised strips of the skin on the back or breast, which is allowed to hang thus until the skin is nipped and the thongs are freed. Some men who do not intend to dance seat themselves near the sun-pole, and small pieces of flesh are cut out in a row from the shoulders of each; these are offered to the being represented by the sun-pole. Women do not savor themselves in the sun-dance, and self-torture and the shedding of blood are not practised in the Kiowa ceremony. Consult Catlin, G., 'North American Indians' (new ed., 2 vols., Philadelphia 1913); Lowrie, R. H., 'The Sun Dance of the Crow Indians' (New York 1915).

SUN-DEW, any herb of the genus Drosera, which is classified near the pitcher-plants and the roses. Several species are found in America. The flowers are very pretty, like that of the saxifrage, five-petaled, and borne at the top of a slender scape, in a bud which are bent downward, the blossom of each day surmounting the arch and facing the sky. They are white or purplish in color. Sun-dews grow in bogs or wet ground, the roots are poorly developed and yet the small plants thrive even in sphagnum; this is because they are flesh-eaters, and live on the nutrient obtained from such insects as they can catch on their foliage; the roots, therefore, serving principally to anchor the plants and supply the large amount of water needed. The leaves, varying in shape in the several species, from round to filiform, are covered thickly on the upper face with wine-red filaments having a glistening drop like dew at the tips. These are stalked glands, destined for a purpose as deadly as that of the tentacles of the octopus. The leaf blades of the Drosera rotundifolia, a common sun dew, are round, and are arranged in a rosette around the base of the flower-scape, the small green woman and approximating resting on the ground. In times of inaction the tentacles radiate in concentric circles and are tipped by their globular translucent glands, which sparkle with a viscid secretion exuded by them. But let a fly light on one of the glands and remain there, glued fast by the viscous fluid, and there is immediately a change in the state of things. In its efforts to release itself, the struggling insect is only besmeared more completely, chokes the organs of respiration and is ultimately smothered. In the meantime, the tentacles, disturbed by the fly, have become excited and have transmitted the stimulus to the other glands so that they all bend toward the tiny body, converging over it, and striving to touch it. They even shift the inert object toward the centre of the leaf-blade, so that the greatest number of tentacles may reach it. Such glands as succeed in touching the meat secrete an acid juice, with the addition of a ferment which is entirely similar to pepsin, and apply this secretion to the fly digesting it, as it were. The glands then absorb the flesh and blood of the meat, and also their own secretions. The tentacles straighten up, the undigested portions of the insect resting on the dry glands are blown away, and the glands soon begin to exude a fresh secretion again, and make themselves ready for a fresh victim. When a large insect is entangled, the leaf-blade itself folds inward slightly, so that a maximum number of tentacles may concentrate upon the food. D. filiformis has erect, very narrow leaves, and when an insect is caught by the glands, the leaves themselves bend toward it. In D. longifolia the leaf-blade enfolds the fly. Sun-dew glands respond by bending to repeated touches, although no object rests upon them. It is only nitrogenous food which is obtained by this digestive process; carbonic acid is assimilated from the air as by other plants. Consult Darwin, C., 'Insectivorous Plants' (1875; new ed., 1900).

SUN-DIAL, an hour-measuring instrument known from the earliest times to the Egyptians, the Chaldaeans, and the Hebrews. It is worthy of remark, however, that no ancient Egyptian sun-dials have been found. Those connected with Egyptian remains have been recognized as all of Greek origin. The Greeks adopted it from the Etruscans, and it was introduced into Rome during the First Punic War. One of the earliest types of sundial found in Egypt, and still in use there, consists of a palm rod set upright in the ground, with a circular arc around it set out with stones to mark the hours as the shadow of the rod traverses the circle. Another more primitive form still in existence in Egypt has a rod laid horizontally in a north-and-south direction on two forked uprights, a short distance above the supply of water in the east and west of the rod are placed two stones or pegs. When the shadow of the rod lies across the westerly peg the day's work begins; when it reaches the easterly peg the day's work is ended.

It was discovered in very early times that a vertical rod could not throw a shadow that would accurately denote time, and the correct inclination of such a rod or the stile of a sun-dial was evidently a matter of experiment before the Greeks furnished the mathematicians with the means of fixing the angle by calculation. This surmise is borne out by the various inclinations found in ancient dials. Some of these were constructed arbitrarily at 45°, an angle having no relation whatever to the latitude of its location.

The first historic sun-dial dates from about 1000 B.C. It was found in Rhodesia, and is believed to be of Semitic origin. Sun-dials are referred to in Grecian literature in 560 B.C., and a certain sun-dial is specifically spoken of as having been set up at Athens by the astronomer Meton in 433 B.C. It is said of the Turks that wherever they build a mosque they place a sun-dial. In China they are everywhere, and small ones which may be carried in the pocket are very common. The correct use of these portable dials depends, of course, upon their accurate orientation when reading them.

Sun-dials have been classified under three headings, according to their superficial form: spherical, cylindrical and plane. The spherical form is the most used; it consists of a hemispherical hollow cut into a rock or built up in that form, the flat of the hemisphere being horizontal. An upright rod was set in
the centre of the hemisphere, pointing to the zenith. The hour marks were cut into the hollow surface. A variation of this type was the cutting away of the front half of the hemisphere. This form of necessity can mark only the hours from 6 A.M. to 6 P.M. An old Roman dial is in the form of a spherical shell of which about two-thirds have been cut away, held upon the shoulders of a herculean figure. Cylindrical dials have the hollow in the shape of a semi-cylinder cut through lengthwise. A rod in the position of the axis of the cylinder throws the shadow. A variation of this form is a semi-cone cut through its axis. The plane dials are too well known to need description.

In the placing of sun-dials another classification comes into play; they may be horizontal or vertical. Many of the latter type are set into or carved upon the walls of churches or other buildings or on stone blocks set upon pillars or pedestals. As a rule, the vertical sun-dials are set to face directly south. Where this is not feasible the gnomon may extend toward the south at the angle of a corner of a building, the hour lines being partly on one façade and partly on the other. In some of the odd pillar types the stone block at the top is cut with many facets like a crystal, with a gnomon on each facet.

The leading principles of dialing may be made intelligible to general readers by the following simple illustration:

Let $PB$, $PD$ represent the earth as a hollow transparent sphere, having an axis $PE$, of the shadow of the axis to fall on the hour on the plane $DCBA$. This diagram has been drawn for the latitude of Glasgow, $55^\circ 52'$, and the plane in its present position would form a horizontal dial for that place; but we may suppose it capable of moving round its axis $AC$, so as to assume different positions in the sphere. If it move round so as to become vertical, that is, at right angles to its position in the figure, we then obtain an erect south dial. The plane may also be made to incline from the meridian either toward the east or west. Thus we have dials of different kinds dependent on the position of the plane with regard to the first meridian, the position of the hour lines of which are all determined by the meridians of the sphere cutting the plane.

We have been considering the earth as the sphere, in our illustration of the nature of dials, but the earth's magnitude is so small compared with the distance of the sun, that no appreciable error will follow in considering a small glass sphere similar to that above described, but placed on the surface of the earth with its axis parallel to that of the earth; then will the sphere show the hour of the day in the manner before specified. The only things absolutely essential for a dial are the axis and the plane, the places of the hour lines having been once determined. Dials may have various forms, many of which are exceedingly curious and intricate, and require for their construction the application of complicated trigonometrical formulas. We shall confine our attention here to the most common, and, at the same time, most useful form, that is, the plane horizontal dial. On the proposed plane, which may be either of marble, slate or brass, draw a straight line $PHS$ for the meridian or 12 o'clock line, and parallel to this draw $12, H, S$, leaving a space between them equal to the thickness of the gnomon.

The gnomon is a thin triangular plate of metal, somewhat similar in shape to the figure $AEB$, the side $AB$ being fixed into the plate of the dial, so that the gnomon shall stand perpendicularly, the line $AE$ being directly north and south.

The line $AE$ is called the style, and the angle $EAB$ is made equal to the latitude of the place for which the dial is constructed. In the case of a vertical dial the angle $EAB$ must be the complement of the latitude, the
line A B the top of the gnomon and the line B E affixed to the dial.

We return again to the consideration of Fig. 2. Draw 6 H 6 perpendicular to 12 H S, and it will be the six o'clock hour line; make the angle 12 H F equal to the latitude of place, and draw 12 F perpendicular to F S, having 12 F equal to 12 F. The line 12 1 2 3 4 is drawn parallel to the line 6 H 6. From the point P draw the lines P 1, P 2, P 3, etc., terminating in the line 12 1 2 3 4, making angles with the line 12 P at the point P of 15°, 30°, 45°, etc., increasing by 15° each line. Next from the centre H draw the lines H 1, H 2, H 3, etc., and thus the hour lines of 1, 2, 3, 4 and 5 P.M. will be found. The hour lines on the other side of the style should now be formed by taking a tracing of the side already formed; the hours are of course numbered differently, and both sides will stand thus, the hour line of both sides corresponding:

1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12.

Here we have carried the hours beyond 6, which was the extent of the construction but found the hour line for 4 and 5 in the morning we have only to produce the hour lines of 4 and 5 in the evening, and in like manner for the hour lines of 7 and 8 in the afternoon, produce the hour lines of 7 and 8 in the morning. The dial gives solar time, and, therefore, the time, according to it, will only agree four days in the year with a well-regulated clock. See Equation.

The orientation of the sun-dial after it is made is a necessity of the first importance if satisfaction is desired. This process is carried out usually at night with the aid of two plum lines one north and the other south of the position in which the dial is to be set. From the Nautical Almanac the time is found at which the polestar crosses the meridian of the place. The two plum lines are brought into a line pointing to the star at that moment. The dial can then be placed in the same line conveniently by daylight. It is usual to erect frames of considerable height to hold the plum lines so that the sighting upward may be the easier. If the location of the pedestal of the dial is chosen beforehand, the frames for the plum lines must be so arranged that both may be moved so as to have the centre of the pedestal in the same line with them and the star.

The sun-dial is daily getting more rare in this age but notwithstanding the superiority of the clock, why has the dial almost everywhere vanished? "If its business use," as has been well observed, "be superseded by more elaborate inventions, its moral use, its beauty, might have pleaded for its continuance. It spoke of moderate labors—of pleasures not protracted after sunset—of temperance and good hours. It was the primitive clock—the horologe of the ancients. Age has not missed it in paradise. It was the measure appropriated for sweet plants and flowers to spring by— for the birds to apportion their silver warblings by— for flocks to pasture and be led to fold by. The shepherd carved it out quaintly in the sun, and, turning philosopher by the very occupation, provided it with mottoes more touching than tombstones."

SUN-DOG: also called Mock-Sun and Parhelion. In meteorology, a bright, luminous area sometimes seen on either side and at the same altitude as the sun. Sun-dogs are found at the points in which the solar halos cut the horizontal, parhelic circle. Thus two sun-dogs are usually seen on either side of the sun, and at equal distances from it, though four are not infrequent. The nearer pair are 22° from the sun and the outer are 46° distant, while fainter sun-dogs are more rarely seen at 50°, 98° and 120°, and even directly opposite the sun. The last is sometimes known as an Anhelion.

Bright areas formed at the intersections of any two circular halos near the sun are sometimes also referred to as sun-dogs and such sometimes are seen directly above and below the sun. The parhelic circle is produced by the reflection of the sun's light from ice prisms or snow crystals whose axes lie in a vertical position — so-called 'Contract Arches' arise from prisms whose axes are horizontal. It is the latter that give rise to sun-dogs which are vertically above and below the sun.

Sun-dogs are usually reddish on the sides toward the sun and they are sometimes greatly elongated along the parhelic circle which produces them. They vary greatly in brightness and distinctness with the variation of the number and arrangement of the ice crystals in the air.

SUN AND LION, Order of, a Persian order founded in 1808 by Shah Path Ali, in imitation of the French Legion of Honor, established about six years previously by Napoleon I, then first consul. It includes five classes.

SUN MOTOR. See Solar Motor.

SUN WORSHIP, a form of nature worship which prevailed in all the ancient civilizations. In numerous primitive religions the sun is not the supreme deity; in many the moon holds the pre-eminence. The mode of reckoning time by moons is more ancient than solar calculation: in the language of the Hottentots, just as in Teutonic, the Moon is hehe, the Sun she she; and rude tribes in both hemispheres still make the moon masculine, the sun feminine: the ancient Germans used to say Hermon (Herrmond, Lord Moon) as the Germans still say Herrgott: on the other hand, as a medieval writer tells us, the sun used to be called Holy Lady: "I knew an old woman who believed the sun to be a great scarce, calling her son its doxling." The aborigines of North America worship the sun; for them the peace-pipe is the gift of the sun; in the council the pipe is always passed.

"Horae non numero nisi sermone" ("I count not the hours unless they be bright") was an ancient dial motto of great beauty and significance.
around, following thus the sun’s course. The Natchez lived under a monarchy and the royal family, children of the Sun, like the race of the Incas of Peru, stood high above the common people. In Mexico the sun was pre-eminent over all the other gods. In the Hebrew sacred books there are solemn denunciations of sun worship, for the heathen all around paid adoration to the luminary; and it is clear from 2 Kings, 5: 19, that some of the kings both of Judah and of Israel favored the worship of the sun.

SUN-YAT-SEN, Chinese revolutionary leader: b. Fatshan, near Canton, 1866. He was graduated (1902) at Hongkong School of Medicine, and started practice at Macao when he became one of the plotters resolved on forcing the Manchu dynasty from power. He fled from Canton after the first failure at revolt and went to Japan, thence to San Francisco. He formed the revolutionary association Kao Lao Hwei and carried on his propaganda all over the world, making the United States his headquarters and domicile. Dr. Sun’s life was jeopardized by the standing reward of $50,000 for his assassination, but the revolution of 1911 in China succeeded, thanks largely to his indefatigable energy and resourcefulness in propagating the work in every country. He was rewarded by being made Provisional President of the new Chinese Republic but resigned in 1912 in favor of Yuan Shih-kai in order to be the dominant influence of the latter into the cause. Sun’s later opposition to Yuan Shih-kai in the Peking Parliament caused his expulsion and he had to flee to Japan. Consult Cantile and Jones, ‘Sun-Yat-Sen, and the Awakening of China’ (3d ed., New York 1913).

SUNBURN (erthema solare or eczema solare), an injured condition of the skin caused by exposure to the action of the heat of the sun’s rays. The resulting conditions vary according to the degree of elevation of the temperature, the character of the medium through which its effect is exerted, length of time the skin is subjected to the action. The effect is productive of an erythematous redness, skin slightly tumified (swollen), with sensation of burning heat. In its course the skin usually desquamates (scales off) and becomes the seat of a “dirty-brownish stain,” which passes off later. Such a condition is brought about by several hours’ exposure of the bare skin to the sun’s rays. Under severe conditions of temperature blistering may arise at times. In the former, ordinary cases a lotion or salve excluding the air from the injury, and to relieve the pain, is applied. Zinc oxide, boric acid, vaseline, etc., are recommended. In severer cases excision arising the same treatment must be used as in scalds or burns.

SUNBURY, sôn’bû-rî, la., borough, county-seat of Northumberland County, on the Susquehanna River, and on the Pennsylvania and the Philadelphia and Reading railroads, about 157 miles north of Philadelphia and 55 miles north of Harrisburg. It was settled in 1772 by Rev. General Lukens and William Maclay. It was incorporated as a borough 24 March 1797. The place was once the site of the Indian village of Shemokin. In 1756 Fort Augusta was erected here as a means of defense against the French and Indians. The city is in a lumbering and coal region. The chief manufacturing establishments are railroad shops, planing mills, silk mills, dye works, sash and door factories, nail factories, a rolling mill and coffin and casket works. It is an important commercial and industrial centre for a large region; extensive coal shipments are made from here. The principal public buildings are the county courthouse, municipal buildings, the Mary M. Packer Hospital, the churches and public schools. The three banks have a combined capital of $500,000. The government is vested in a chief burglar, a council of 16 members, who hold office two years. A small stream separates Sunbury and East Sunbury; the boroughs are one in industrial and commercial interests, but have independent municipal governments. Pop. about 16,000.

SUNDA (sûn’da) ISLANDS, a group of islands in the Indian Ocean, comprising three minor groups, namely, (1) the Great Sunda Islands, to which belong, Sumatra, Borneo, Celebes, Java, Madura, Banka and Billiton; (2) the Lesser Sunda Islands, comprising nine islands of smaller extent, forming the Sunda Group, all forming part of the Malay or East Indian Archipelago. The flora is exceedingly rich and varied. This is the home of sugar-cane and many of the spices, and the different altitudes from coasts upward produce an exceptional variety of plant-life. Some districts, as in Sumatra, reach high elevations, others consist chiefly of grassy plains, or forest-covered slopes.

SUNDA STRAIT, East Indies, the channel which separates the island of Java from Sumatra. It is from 20 to 100 miles wide, and contains a number of volcanic islands, the most noted of which is Krakatao (q.v.). The strait is an important commercial channel.

SUNDERBANS, soon’där-bânz, or SUNDERBHUNDS, soon’dër-bûn’dz, India, the alluvial islet region lying around the mouths of the Ganges River (q.v.), and forming the lower part of the delta. It stretches for 175 miles along the coast, and has an area of 8,000 square miles. The region is intersected by a network of innumerable channels and backwaters, many of which are navigable. The intervening islands are largely marshy, and covered with dense forest jungle abounding in wild animals, snakes, crocodiles, tigers and leopards. The unhealthy climate has hitherto defeated all attempts at reclamation.

SUNDAY, William Ashley, American evangelist: b. Ames, Iowa, 19 Nov. 1863. He was educated at the high school, Nevada, Iowa, and studied at Northwestern University. From 1883–90 he was a professional baseball player in the Chicago, Pittsburgh and Philadelphia teams of the National League. He became assistant-secretary Y. M. C. A at Chicago (1891–95) and started his career as evangelist in 1896. In 1903 he was ordained a Presbyterian minister by the Chicago Presbytery. He has held evangelistic meetings in many of the cities of the United States, drawing large audiences and securing great numbers of converts.

SUNDAY, the Christian weekly festival, by theologians associated with the Jewish Sabbath
SUNDAY

(see SABBATH), while its observance is often enforced by the citation of the Fourth Commandment in the Decalogue. While the Christian Church has never identified Sunday with the Jewish Sabbath, it has always quoted the Fourth Commandment as sanctioning, if not enacting, rest and relaxation from labor in one day out of every seven. When the Church was made a department of civil state by the Christian emperors of Rome, the observance of Sunday was enforced by civil statute. When the Roman Empire passed away, and the office of pontifex maximus, once held by the emperor of Rome, was claimed by the bishop of Rome, Sunday observance was enforced by ecclesiastical as well as civil law. The Third Council of Orleans 538 forbade all rural work on Sunday. Pope Gregory I made at Rome the same law as had been passed in 578 by the Council of Auxerre:

"On the Lord's Day it is not permitted to yoke oxen or to perform any other work, excepting for approved reasons." Charlemagne in 813 enacted that on the Lord's Day all servile labor should be abstained from. What that meant in practice is shown by what was done in England during the Saxon monarchy up to the time of Edward the Confessor (whose Sunday law is dated 1056), abstention from marketings on Sunday and from popular meetings was enforced under penalty of a fine. Equally strict was the Sunday legislation which followed the Norman Conquest. The mediæval Sunday laws in England were but the expansion of the Saxon laws. In 1281 a.d. John Peckham, archbishop of Canterbury, explained the Fourth Commandment as follows:

"In the commandment 'remember that thou keep holy the Sabbath day,' Christian worship is enjoined, to which laymen as well as clerks are bound; and here we are to know that the obligation to observe the legal Sabbath, according to the form of the Old Testament, is at an end, together with the other ceremonies in that; to which in the New Testament hath succeeded the custom of spending the Lord's Day, and other solemn days appointed by the authority of the Church, in the worship of God; and the manner of spending these days is not to be taken from the superstition of the Jews, but from the canonical institutes."

A statute of the 26th of Edward III runs as follows: "Item, it is accorded and established, that showing of woolls shall be made at the stable every day of the week, except the Sunday and solemn feasts of the year."

In 1359 a.d. Islep, archbishop of Canterbury, issued the following to his clergy: "Whereas, the most excellent prince, our lord, the King of England, is now going to make an expedition in foreign parts with his army for the recovery of his right, exposing himself as a soldier to the doubtful event of war, the issue whereof is in the hand of God; we who have hitherto lived under his protection are, by the divine favor shining on us, admonished to betake ourselves to prayer, as well for the safety of every one of his men as for the safety of our own person; and as a golden opportunity of doing us good fortune should invade us (which God forbid), our confession and reproach should be the greater. But, though it is provided by sanction of law and canon that all Lord's days be observed, as the Christian race, that neither markets, negotiations or courts, public or private, ecclesiastical or secular, be kept, or any country work done on these days, yet we are clearly to our heart's grief, informed that a detestable, nay, damnable perverseness has prevailed, insomuch that in many places markets not only for victuals, but other negociations (which can scarce be without frauds and deceit), unlawful meetings of men who neglect their churches, various tumults and other occasions of evil the Christian emperors of Rome, the observance of Sunday was enforced by civil statute. When the Roman Empire passed away, and the office of pontifex maximus, once held by the emperor of Rome, was claimed by the bishop of Rome, Sunday observance was enforced by ecclesiastical as well as civil law. The Third Council of Orleans 538 forbade all rural work on Sunday. Pope Gregory I made at Rome the same law as had been passed in 578 by the Council of Auxerre:

"On the Lord's Day it is not permitted to yoke oxen or to perform any other work, excepting for approved reasons." Charlemagne in 813 enacted that on the Lord's Day all servile labor should be abstained from. What that meant in practice is shown by what was done in England during the Saxon monarchy up to the time of Edward the Confessor (whose Sunday law is dated 1056), abstention from marketings on Sunday and from popular meetings was enforced under penalty of a fine. Equally strict was the Sunday legislation which followed the Norman Conquest. The mediæval Sunday laws in England were but the expansion of the Saxon laws. In 1281 a.d. John Peckham, archbishop of Canterbury, explained the Fourth Commandment as follows:

"In the commandment 'remember that thou keep holy the Sabbath day,' Christian worship is enjoined, to which laymen as well as clerks are bound; and here we are to know that the obligation to observe the legal Sabbath, according to the form of the Old Testament, is at an end, together with the other ceremonies in that; to which in the New Testament hath succeeded the custom of spending the Lord's Day, and other solemn days appointed by the authority of the Church, in the worship of God; and the manner of spending these days is not to be taken from the superstition of the Jews, but from the canonical institutes."

A statute of the 26th of Edward III runs as follows: "Item, it is accorded and established, that showing of woolls shall be made at the stable every day of the week, except the Sunday and solemn feasts of the year."

In 1359 a.d. Islep, archbishop of Canterbury, issued the following to his clergy: "Whereas, the most excellent prince, our lord, the King of England, is now going to make an expedition in foreign parts with his army for the recovery of his right, exposing himself as a soldier to the doubtful event of war, the issue whereof is in the hand of God; we who have hitherto lived under his protection are, by the divine favor shining on us, admonished to betake ourselves to prayer, as well for the safety of every one of his men as for the safety of our own person; and as a golden opportunity of doing us good fortune should invade us (which God forbid), our confession and reproach should be the greater. But, though it is provided by sanction of law and canon that all Lord's days be observed, as the Christian race, that neither markets, negotiations or courts, public or private, ecclesiastical or secular, be kept, or
Lord, or on the feast of Corpus Christi to command or cause to be sold, or place or put on any one's feet or legs, any shoes, hose or galoches, under the penalty of the forfeiture of their souls and a fine of ten shillings for every offense; a third part to go to the king, a third to the governors of the guild (mestier) of cordwains, and the residue to the informer. In 1523 this act was repealed by Henry VIII (1509-1547).

On coming to the throne in 1547, Edward VI issued the following injunctions: *Whereas in our time, God is more offended than pleased, more dishonored than honored, upon the holy day (Sunday), because of idleness, pride, drunkenness, quarrelling and brawling, which are most used in such days; people nevertheless persuading themselves sufficiently to honor God on that day if they hear mass and service, though they understand nothing to their edifying; therefore all the king's faithful and loving subjects shall from henceforth celebrate and keep their holy day (Sunday) according to God's holy will and pleasure, that is in hearing the Word of God read and taught, in private and public prayers, with thanksgiving, showings of offenses to God, and amendment of the same, in reconciling themselves charitably to their neighbors, where displeasure hath been, in oftentimes receiving the communion of the very body and blood of Christ, in visiting the poor and sick, and in using all soberness and godly conversation.*

Elizabeth put forth the following injunction touching Sunday: *All the queen's faithful and loving subjects shall, from henceforth celebrate and keep their holyday according to God's will and pleasure; yet notwithstanding, all parsons, vicars and curates shall teach and declare unto their parishioners, that they may with a safe and quiet conscience, after their common prayer in the time of harvest, labor upon the holy and festival days, and save that thing which God hath sent . . . in every parish three or four discreet men, which tender God's glory, and his true religion, shall be appointed by the ordinaries diligently; and that no parishioner duly resort to their church upon all Sundays and holy days, and there to continue the whole time of the godly service; and all such as shall be found slack and negligent in resorting to the church, having no great or urgent cause of absence, they shall straightly call upon them, and after due admonition if they amend not, they shall denounce them to the ordinary.*

Under the Puritan influences attempts were made to bring about a too strict observance of Sunday. To counteract this Charles I republished an injunction issued by his father, James I, in which he declared: *As for our good people's liberty and religion, we do hereby declare it is, that after the end of divine service our good people be not disturbed, letted or discouraged from any lawful recreation, such as dancing, either men or women, archery for men, leaping, vaulting or any other such harmless recreation, or for playing at any sport, music, morris dances, and the setting up of May poles and other sports therewith used; so as the same be had in due and convenient time without impediment or neglect of divine service; and that women shall have leave to carry rushes to church for the decorating of it, according to their old custom. But withall we do here account still as prohibited all unlawful games to be used on Sundays, only as bear and bull baits, interludes, and at all times in the meaner sort of meals on the day aforesaid.*

The act of Charles II (1670) was the law of the American colonies up to the time of the Revolution, and so became the basis of the American Sunday laws. It runs as follows: *For the better observance of holy the Lord's day, commonly called Sunday: be it enacted by the king's most excellent Majesty, and by and with the advice and consent of the lords, spiritual and temporal, and of the commons in this present Parliament assembled, and by the authority of the same, that all the laws enacted and in force concerning the observation of the day, and repairing to the church thereon, be carefully put in execution; and that all and every person and persons whatsoever shall upon every Lord's day apply themselves to the observation of the same, by exercising themselves thereon in the duties of piety and true religion, publicly and privately; and that no tradesman artificer, workman or other person or persons entertaining any worldly labor or business or work of their ordinary callings upon the Lord's day, or any part thereof (works of necessity and charity only excepted), and that every person being of the age of fourteen years or upwards offending in the premises shall, for every such offense, forfeit the sum of five shillings; and that no person or persons whatsoever shall publicly cry, show forth, or expose for sale any wares, merchandise, fruit, bread, goods or chattels whatsoever, upon the Lord's day or any part thereof, upon pain that every person so offending shall forfeit the same goods so cried or showed forth or exposed for sale. And it is further enacted that no drover, horse-courser, waggoner, butcher, higgler — they or any of their servants shall travel or come into his or her inn or lodging upon the Lord's day, or any part thereof, upon pain that each and every such offender shall forfeit twenty shillings for every such offense. And that no person or persons shall use, employ, or travel upon the Lord's day with any boat, wherry, lighter or barge, except to be upon extraordinary occasion to be allowed by some justice of the peace of the county, or some head officer, or some justice of the peace of the city, borough or town corporate, where the deed shall be committed, upon pain that every person so offending shall forfeit and lose the sum of five shillings for every such offense.*

The Lord's day legislation of Cromwellian days was as distinct and detailed as a fragment from Leviticus, as is shown in the following extract from an act of Parliament dated 1656: *Every person grining or causing to be ground any corn or grain in any mill, or causing any fulling or other mills to work upon the day aforesaid; and every person working in the washing, whiting or driving of clothes, thread or yarn, or causing such work to be done, upon the day aforesaid; every person setting up, burning or branding beasts upon the day aforesaid; every person gathering of rates, loans, taxations or other payments upon the day aforesaid (except to the use of the poor in the public collections); every chandler melting, or for that purpose using, wax belonging to his calling; and every common
brewer and baker, brewing and baking, or causing bread to be baked, or beer or ale to be brewed upon the day aforesaid; and every butcher killing any cattle, and every butcher, c offermonger, poulterer, herb seller, cordwainer, shoemaker or other person selling, exposing or offering to sell any of their wares or commodities, upon the day aforesaid; all tailors and other tradesmen, fitting or going to fit, or carry any wearing apparel or other things; and baker, bakers, runnemen, persons keeping, using or being present upon the day aforesaid at any fairs, markets, wakes, revels, wrestling, shootings, leaping, bowling, ringing of bells for pleasure or upon any other occasion (saving for calling people together for the public worship), feasts, church ale, May poles, gaming, bear-baiting, bull-baiting, or any other sports and pastimes; all persons unnecessarily walking in the church or church-yards, or elsewhere in the time of public worship, and all persons vainly and profanely walking, on the day aforesaid; and all persons traveling, carrying burthens or doing any worldly labor or work of their ordinary calling on the day aforesaid, shall be deemed guilty of profaning the Lord’s day.

In the 17th century a number of dissenters fled from England and reached America in 1620, and settled at New Plymouth. In 1629 another band from England joined them. Thus the establishment of Puritanism in America. The theocracy of the Hebrews furnished the model after which their civil government was constituted. Their idea of Sunday was summed up in the enactment of 10 June 1650, passed by the Plymouth general court: Further be it enacted, that whosoever shall profane the Lord’s day by doing any servile work, or any such like abuses, shall forfeit for every such default ten shillings, or be whipped.

Profanation of the Lord’s day included traveling, loitering at the door of a meeting house, drinking in an inn, staying at home instead of attending church and it was also enacted by the court, that “if any in any lazy, slothful or profane way doth neglect to come to the public worship of God, shall for be forfeit for every such default ten shillings, or be publicly whipped.

In Massachusetts the laws were equally strict.

In 1716 Sunday desecration appears to have been on the increase, since we are told: “Many persons do presume to work and travel on the said day” so that the authorities saw it fit to increase the penalty for “working or playing” to 10 shillings, and that for traveling to 20 shillings for the first offense. For the second offense these fines were doubled and the parties made to give sureties for good behavior in the future. A month’s continued absence from the public Sunday services was also made punishable by fines of three hours in the stocks or cage. In 1727, the fine for “working or playing” was increased to 15 shillings, and that for traveling to 30 shillings for the first offense, and for the second, three pounds. If the offender failed to pay the fine, the offender to be imprisoned in the county jail not to exceed five days. At this time, also, funerals, since they induced “great profanation of Sunday, by the travel and passing of children and servants in the streets, were prohibited, except in extreme cases, and then under license from a civil officer of the town. The director of a funeral transgressing this was to be fined 40 shillings, and the sexton or grave-digger 20 shillings. Shors for the retailing of strong drinks were also to be searched by the proper officers, and if any were found there drinking, the proprietor and the drinker were each to pay five shillings.

In 1760 all former laws relative to Sunday gave way to a new code, the provisions of which were as follows: Work or play on land or water, is fined not less than 10 nor more than 20 shillings. Traveling by any one except in extremity and then only far enough for immediate relief, is liable to the same penalty. Licensed public-house keepers are forbidden to entertain any except travelers, strangers and lodgers in their houses or about their premises, for the purpose of drinking, playing, lounging or doing any secular business whatever, on penalty of 10 shillings; the persons lounging, etc., also paying not less than five shillings. On the second conviction the innkeeper is made to pay 20 shillings and on the third offense to lose his license. Loitering, walking or gathering in companies in streets, fields, orchards, lanes, whatsoever is prohibited on pain of five shillings fine; and on a second conviction the offender is required to give bail for future obedience. Absence from public service for one month is fined 10 shillings. No one is to assist at any funeral, not even to ring a bell, unless it be a licensed funeral, on penalty of 20 shillings fine. In Boston, however, a funeral might be attended after sunset without a license. The observance of the Sunday was to commence from sunset on Saturday. Twelve wardens were appointed in each town to execute these laws; these were to look after all infringements, enter all suspected places, examine or enquire after all suspected persons, etc. In Boston they were to patrol the streets every Sunday (very stormy or cold days excepted), and diligently watch and search for offenders. In case any one convicted on any point in this code failed to pay his fine at once he was to be committed to the common jail, not less than five, nor more than 10 days. These laws were to be read at the March meeting of the towns each year.

Practically all the States of the American Union have laws prohibiting Sunday work; but these laws are practically a dead letter. In Arizona and California, however, there are no special Sunday laws. In all other States there are laws, in one form or another, providing for the Sunday-closing of saloons and general places of business, exclusive of drug stores, restaurants and businesses of prime necessity to the general comfort of the community. These laws are pretty generally observed. In some places even harbor shops are closed.

SUNDAY CONSTABLE. See Town and Town Meetings.
SUNDAY SCHOOLS, meetings or gatherings in which religious instruction is given to children and young people, usually orally and on Sundays. Such schools are sometimes also known as Bible classes, because the Bible is the textbook in frequent use and often the Bible and the Christian doctrine lessons are arranged in a catechetical form and hence are the name of the textbook used, catechism, which is sometimes applied to the class or school itself as such a book. More commonly, however, a Bible class is one of a series of classes in a Sunday school, frequently being a class for adults and older scholars. The work of teaching religion to classes or in schools was practised in very ancient times (Gen. xiv, 14) and by the ministers of God, or their appointed assistants, whenever conditions were such that the young were not taught in their own homes (Deut. xxxi, 10-13). The study of the law was of obligation; religious schools existed in connection with the synagogues. The catechetical method was at first in general use.

Early Christian Doctrine Schools.—The apostles, or certain persons appointed for the work of giving instruction to the catechumens. The religious school, among Christians, seems to have had first place; before the books of the Bible were collected as they now exist, the life of Christ had been taught orally. As Christianity extended and schools came under the control of the Christians as nearly all the teachers were Christians, so the religious instruction became a part of the regular work of the school. The differences which arose at the time of Luther (q.v.) led to the establishment of classes and schools for teaching the religious beliefs of different churches. In many cases the religious teaching was continued in the schools and the new classes formed were for the poor and those, both young and old, who were not well instructed. Luther and his followers established such schools. Saint Charles Borromeo (q.v.) was one of the most zealous in founding Sunday schools in all parts of his archdiocese of Milan. He succeeded in arousing the enthusiasm and in securing the cooperation of the laity, men and women, so that he had a large number of teachers. In order to unite the workers and furnish a means of training them for the work, he established an organization called the "Confraternity of Christian Doctrine." Besides the teachers who were members of this Confraternity, there were also others, who were called Fishers, whose duty was to gather the children and the ignorant and bring them to the places appointed, on Sundays or on week days. At the death of Saint Charles there were in his diocese alone nearly 4000 members of the Confraternity. They taught in 740 Sunday schools and had over 40,000 pupils. Those receiving religious instruction in the regular schools were not included in this number. This Confraternity still exists. In England there is a large membership. It was introduced into the United States in 1902 and established in the archdiocese of New York by the Roman Catholic archbishop, Michael Augustine Corrigan.

Modern Sunday Schools.—Robert Raikes (q.v.) of Gloucester, England, is the founder of the modern Protestant Sunday school. He first thought of the work in connection with a number of children of wretched appearance whom he saw playing in the suburb of the city where he lived. He was informed by an instructor of a Protestant church that on Sundays, when the children were released from work, and the few who enjoyed the benefit of any instruction during the week were free from school, they presented a more attractive sight of the universe. Education immediately suggested to him the idea that the profession of the day might be prevented by keeping them occupied; and he engaged several women, who kept schools in the neighborhood, to receive such children as he should send to them on Sundays and instruct them in reading and the catechism, paying each of them a shilling for her day's work. He soon collected a considerable number of children, distributed books among them, gave them advice, settled their quarrels. The effects of his benevolent exertions were so beneficial that his example was followed by other charitable persons in different quarters of the city and in a few years Sunday schools were established in almost every part of Great Britain. Raikes made his first experiment in 1781 and in 1786 it was estimated that 250,000 children were receiving instruction in Sunday schools. A Sunday school society was formed in 1785 and the members were encouraged to give their personal service gratuitously. In 1803 the first Sunday school union was formed in London and the example was soon imitated in many large towns and some of the counties. The Scotch Sabbath schools (first established in Edinburgh in 1782) arose from the English Sunday schools, but from the first were more entirely devoted to religious instruction than the Sunday schools of England. The first Sunday schools united secular with religious instruction. Sunday schools were established in Protestant churches in Scotland, Ireland and America, in the years immediately following their establishment in England; the Scotch Society for Promoting Religious Instruction Among the Poor was formed in 1796 and the Irish Sunday School Society was founded in 1809, though a system of Sunday teaching had prevailed in Ireland for some years previously. In later times Sunday schools increased rapidly in connection with all Protestant churches throughout the world. The Sunday school movement was not at first looked upon with favor by the people of New England. It was regarded as a menace to the sacredness of the Sabbath and also as an infringement of the home duties. The Protestant Sunday school, as it exists to-day in the United States, may be said to have had its real beginning in Philadelphia 19 Dec. 1790, when 12 persons held a meeting and decided to begin the work. Sunday schools had been established in the United States shortly after Raikes had begun his work but they existed more as local institutions. On 11 Jan. 1791 a society was established in Philadelphia which had for its object the support of Sunday schools, to whom he addressed himself, president of the society was Bishop William White and Matthew Carey was the secretary. In New York 13 Jan. 1816, a woman's society for the promotion of the work and in the same place, on the 20th of February of the same year, a society of men was organized for the
SUNDAY SCHOOLS

same purpose. The American Sunday School Union is the outgrowth of the Sunday and Adult School Union, established in Philadelphia in 1817. The new and broader organization took definite form 24 May 1824. On the 75th anniversary, the American Sunday School Union had 100,928 Sunday schools with a membership of 4,070,346 pupils and 578,680 teachers. It had distributed literature amounting to near $10,000,000. The first national convention was held in Chatham Street Chapel, New York, 3 Oct. 1832. National conventions were held 23 May 1833 and 22 Feb. 1859, in Philadelphia; 29 April 1869, Newark, N. J.; 16 April 1872, Indianapolis, Ind.; 11 May 1875, Baltimore, Md. At the Baltimore meeting the convention took upon itself the name international, to which title it had a right on account of the enlargement of the work both in aim and territory. On 1 July 1889 a world's convention was held in London. Other world's conventions have been held in Saint Louis, Mo., 3 Sept. 1893; London 11 July 1898. The organization embraces, besides the usual executive officers, lesson committees and different department work, all of which are held at annual State conventions, county conventions and city conventions. The department of field workers is most important. In fact their main work is the financing of missionaries in sparsely settled and neglected localities where they found and foster evangelical but undenominational Sunday schools. Morris K. Jesup, who was for many years the president; Gen. O. O. Howard, Jay Cooke, William E. Dodge, Louis Klaiber and other prominent men have taken a great interest in the Union's work. In the decade ending 1917, they organized over 17,000 new Sunday schools, reorganized 7,000, besides aiding several thousand public schools. The Chautauqua (q.v.) has been a great aid in the enlargement of the work. In 1908 the Protestant Sunday schools in the United States, including Hawaii and Porto Rico, numbered 140,739, with a membership of 11,355,000 pupils and officers and teachers numbering 1,305,000. In 1917 the Protestant and miscellaneous Sunday schools had over 19,000,000 scholars enrolled and the Catholic schools 2,850,000 more; the Methodist group was the largest, comprising 4,900,000 pupils and 300,000 members, followed with 3,800,000; Presbyterian, 2,000,000; Lutheran, 1,000,000; Disciples, 940,000; Congregationalist, 750,000; and Episcopal, Reformed and United Brethren, each nearly 500,000.

All the teaching orders in the Roman Catholic Church, in all countries, give religious instruction in the regular schools, and, when necessary, classes are organized and held on Sundays. The Sunday classes are graded and the regular school classes. The founder of the first normal school for the training of teachers, Saint John Baptist de La Salle was most earnest in having his teachers prepare themselves well for the work of teaching Christian doctrine. The members of his order (popular name, Christian Brothers) have charge of many Sunday schools. Both Protestants and Roman Catholics have established training classes and normal schools for Sunday school teachers. In New York, in 1914, under the auspices of the Confraternity of Christian Doctrine, a training school for teachers in the Roman Catholic Sunday school was established, and affiliated with it are local training classes.

Conventions and Conferences.—The Protestant Sunday School conventions, international, national, State and county, are most inspiring and educational. The question brought home to the members, most forcibly, and at all the conventions, is that the Sunday school is a necessary feeder of the Church, that to have the adult a communicant, the child must be instructed. As a direct result of the great conventions there has grown up a vast Sunday school literature, the churches have been arranged so as to provide suitable meeting places for the Sunday schools. The Sunday school terms are also a center of interest of the conventions and conferences. In the Roman Catholic Church every educational convention, congress, or conference, has for its beginning and end, the subject of Christian doctrine. Sunday school conferences have been held at the Eastern and Western Roman Catholic seminaries, and other cities have had, for some years, regular annual Sunday school conventions.

International Lessons.—In 1872 at the national Sunday school convention in Indianapolis, the plan of having a series of uniform Bible lessons was proposed and met with favor. The lessons were adopted by the Sunday schools of Canada and England, and came into use in many of the Protestant English-speaking Sunday schools of the world. Several periodicals and a large number of books are published as aids for the International Sunday school lessons. Another plan of Bible lessons in use in many parts of the United States is the Blakeslee or inductive system. In the Roman Catholic churches the system in general is based upon preparation for the sacraments (q.v.). Bible study is correlated with the catechism lessons. In addition to the general system, in many dioceses there is a prescribed course of study for the Christian doctrine work (New York, Philadelphia, Brooklyn, etc.). The Jews have regular courses of study for their Sunday schools, which in the United States are conducted by the Orthodox.

SUNDERLAND, Jabez Thomas, American Unitarian clergyman: b. Yorkshire, England, 11 Feb. 1842. He was graduated from the University of Chicago in 1867 and from the Union Baptist Theological Seminary in 1870. He was editor of 'The Unitarian Monthly' 1887-1907 and has been pastor in Milwaukee, Chicago, Ann Arbor, Oakland, Cal., London, England, Toronto, Ontario, Hartford, Conn., and Poughkeepsie, N. Y. He has been director of the American Unitarian Association, secretary of the Western Unitarian Conference, president of the Michigan Unitarian Conference and non-resident lecturer on the Religions of India in the Meadville (Pa.) Theological School. He is a member of the Michigan Authors Club. Has the following honorary degrees: A.B., A.M. and B.D. from the University of Chicago and D.D. (1914) from Tufts College. He was sent to India, 1895-96, by the British and Foreign Unitarian Association, to study the educational, social and religious conditions of the Indian people, and made an extended report on the same on his return to London. In 1913-14 was Billings Lecturer of the American Unitarian Association in Japan, China, Ceylon and India. Was president of the All-India Theistic Congress, held 1912 by the long or mangle faction and contributed reviews and other periodicals in the United States, Canada, England and India. He is author of 'A Rational Faith' (1879); 'What is the Bible' (1878); 'The Liberal Ministry' (1889); 'Home Travel in Bible Lands' (1894); 'A College Town Pulpit' (1895); 'Liberal Religion in India' (1896); 'A Pacific Coast Pulpit' (1898); 'Travel and Life in Palestine' (1900); 'James Martineau' (1905); 'The Spark of Life in the Cloud' (1906); 'India as a World Religion' (1913); 'Liberal Religion as a World Movement' (1913); 'Military Preparedness the World's Menace' (1916).

SUNDERLAND, England, a seaport town and parliamentary borough of Durham, at the mouth of the Wear, 13 miles northeast of the city of Durham and 12 miles southeast of Newcastel-upon-Tyne. The chief buildings are the magnificent Town Hall, Museum, Art Gallery, Libraries and the old parish church of Saint Peter's, on the site of the monastery in which the venerable Bede was educated. Sir Joseph Swan the electrician ('Ediswan') was born here. Two lighthouses stand on the entrance of the excellent harbor. The industrial works include shipbuilding establishments, marine engine works, bottle, pottery and rope factories, coal mines, iron works, paper mills, anchor and chainworks. Coal is the chief export. The limonite are timber and grain, together with materials for use in manufactures, and provisions. These are brought from Baltic ports and Holland. Pop. about 166,000.

SUNFISH, a fresh-water fish of the family Centrarchidae, closely related to the perches (Percidae) and including also the black bass, crappie, and calico bass. These fishes are among the most characteristic of the fresh waters of the United States, where all of the 12 genera and 30 species are found, and of these only one (Archoplites interruptus) occurs west of the Rocky Mountains. Because of their abundance, beautiful colors and forms, interesting habits, courage and gameness, they are perhaps the best known and most esteemed of fresh-water fishes. Most of the true sunfishes belong to the genus Amphiphractus and E. gibbosus, and the different species are not readily defined without a long technical description; but to the layman, or rather boy, all are known collectively as *sunnies*. The commonest and most generally distributed species is the Allegheny Mountains is E. gibbosus, one of the brilliant beauties of our clear brooks and ponds, the type of piscine courage and pugnacity, not fearing to assault any fish that approaches its nest, and itself proof against attacks even from pickerel. Like other sunfishes, it builds a nest of cleaned pebbles on a warm sunny bottom in shallow water, and the male stands guard over the eggs until they hatch and the young are able to care for themselves. This is the boy's favorite game-fish, and it is an excellent morsel on the table. An equally beautiful and larger species, abundant in more sluggish waters throughout the same range and westward, is the blue sunfish (L. pallidus). The long-eared sunfish (L. auritus) is distinguished by a white spot between the eye and the gill cover. The spotted sunfish (Enneacanthus gloriosus) is a most beautiful little fish with gracefully flowing fins and brilliantly spotted translucent body. A large marine sunfish is the prevailing species (Mola mola) of the plectognath family.
Molidae. It is almost circular in form, and the dorsal and anal fins project posteriorly, with the caudal between. The posterior part of the body looks as if it had been cut square off and then the tail replaced, and something like this actually happens in the development of the young. On each side, near the centre, is a small, penniserrate, and forked, finnion; the gills are arranged in comb-like fringes. It attains a large size, four or five feet, in length and three or four feet in depth, with a weight of several hundred pounds; the flesh is white, tough, and a disagreeable odor, unfit for food, and remarkably elastic, the last property depending on the great amount of yellow elastic fibre, interlaced in an intricate manner, almost to the exclusion of white fibre and muscle. It is grayish above and whitish below, with a silvery lustre when alive, and phosphorescent at night, which, with the rounded form, has given rise to a sailor’s name, moonfish. It is sluggish in its motions, and is often seen asleep at the surface; when swimming, it is said to move round like a wheel, and to be able to float with the head and eyes above the surface; the liver is very fat, and its oil is used for lubricating purposes on board ship, and for sprains and bruises among fishermen. Sailors fasten lines from the elastic subdermal tissue. In some seasons it is common in summer in Massachusetts and New York bays, and feeds partly if not principally on medusae or jellyfishes. There is probably no fish more infected by parasites, internally and externally; the flesh and intestines contain many entozoa, and the skin is studded with crustacean parasites. Consult Gunther, ‘Introduction of Fishes’ (Edinburgh 1880); Bollman, ‘Review of Sunfishes’ (Reprint, United States Fish Commission, Washington 1892); Abbott, ‘Naturalist’s Rambles About Home’ (New York 1887); Dean, Bashford, ‘Fishes, Living and Fossil’ (New York 1895).

**SUNFLOWER**. The common name of the New World plants belonging to the large composite genus Helianthus; so called because the heads are likened to the sun. The robust annual sunflowers (Helianthus annuus), native to the prairies of the American West, where they grow over large tracts, sometimes so tall that they hide a horseman riding among them, are often planted as a coarse but brilliant ornamental plant good for concealing fences and the like. The leaves are numerous, rough, very large, and somewhat heart-shaped; the flowers sometimes measure a foot in diameter, generally nodding, and inclining to the sun. The disc is very broad and brownish, and its tubular florets develop four-sided very oily achenes, which are a tid-bit for the Tatars, have been used somewhat for food by the American aborigines, and are the main resource of some seed-eating animals and birds. In Russia, and in some modern gardens, sunflowers are grown solely for these fruits, which form a valuable food for poultry, and yield an oil, useful for either illuminating or soap-making. They are said also to be a remedy for beginnings of boracic spots. H. angulosus has narrow graceful leaves, and brown, disked flowers, and is quite apt to bloom from top to bottom, a distance of some 10 feet. H. dissectifolius var. multiflora is one of the best for cultivation, being not so coarse as other species, and having long-stemmed, clear-yellow flowers, sometimes double, and about three inches across. H. mollis is also interesting, for its soft, white velvety foliage, and stands only about five feet high. H. subtilerous, the Indian potato, has thick lanceolate leaves, and fleshy roots, which are thick, and edible. It is found on the Northwestern prairies. H. tuberosus, with a wider range, has ovate leaves, and fleshy thickened rootstalks bearing the tubers called Jerusalem artichokes. It often grows along roadsides in the East, having been cultivated, doubtless, by the aborigines, and is now largely grown as a fodder for livestock, especially valuable in dry seasons, and as a vegetable for fall.

**SUNFLOWER STATE**, a popular nickname for the State of Kansas, so named from its prolific growth of sunflowers.

**SUNGA.** See INDIAN HUMPED CATTLE.

**SUNGARIA, soon-gâr-é-â, or DZUNGARIA, a region of central Asia, once an independent kingdom. It is not well delimited but comprises generally the district of East Turkestan north of the Tarim Basin and between the Altai and the Tian-Shan mountains, west of Mongolia. In the 17th century the Sungarians extended their power over a region much greater than that above indicated. In 1670 the Chinese overran the country but were driven out after 40 years, when the Sungarians re-established their independence. The new kingdom did not last long, however, for in 1759 the Chinese conquered and annexed it to their empire. Chinese colonists were thereafter sent there in great numbers.

**SUNIUM, su-nil-fim, or CAPE COLONNA, Greece, a promontory forming the southernmost point of Attica, 28 miles southeast of Athens. It consists of a mountain or hill which in ancient times was fortified and crowned by a marble temple of Athena. Portions of the walls and 13 of the columns of the temple still remain. At the foot of the mountain lay the silver-mining town of Sunium.

**SUNKEN BELL, The.** Gerhart Hauptmann’s ‘Versunkene Glocke’ (‘The Sunken Bell’) (1896) is commonly supposed to be the poet’s elegy on the failure of the hopes which he had set upon the attempt to adapt naturalistic methods to the treatment of an historical subject in ‘Florian Geyer’ (first played 4 Jan. 1896). Quite as probably, however, Hauptmann symbolized in this fairy drama a mood to which poets as such are no strangers, even without the chagrin of recent defeat; the melancholy sense that ascent to spiritual heights is toilsome and is impeded by fetters to the lower earth. Moreover, there are spirits of the depths as well as of the heights.

The bell-founder’s wife, driven by his supreme ambition, to place a bell in a mountain chapel, by the malice of a wood-sprite who cannot abide the ringing of it, and despairing he plunges into the abyss which engulfs the chime, becomes the product of his WesternHeart, an unesthetic wife can give him neither comfort nor the courage to live. Both come to him from a mountain elf, Rautendelein. In association with her, he plans a new masterpiece,
SUNN HEMP—SUNSTROKE

half church, half temple to the sun, but he is not destined to accomplish his design. The humdrum dwellers in the valley persecute him as a renegade; the wood-sprites assail him in hostility like Loki's to Balder; the tolling of his submersed bell recalls him to where he with childlike expectation failed of his goal. He repulses Rautendelein and hastens below—but only to return and discover, a moment before he breathes his last, that his proper dwelling place is with her on the heights, and that the nether sphere, the realm of slavery and of death, is that from which no man can escape.

The play, rich in elements derived from German folklore, with some reminiscences of classical mythology, is enhanced by the contrast of naturalism and fantasy, and contains, along with some hollowness, the most intense and musical poetry that its gifted author has ever written. Translated by Mary Harned in 'Poet Lore' (Vol. X., 1898), by C. H. Meltzer (Garden City, 1915), and by Ludwig Lewisohn (in 'The Dramatic Works of Gerhart Hauptmann', New York 1913-15). Edited by T. S. Baker (New York 1901). Cf. Ludwig Lewisohn, 'The Modern Drama' (New York 1915).

WILLIAM G. HOWARD.

SUNN HEMP. See Fibre.

SUNNAH, sün'a, SONNA, or SOON-NUT, the oral teachings of Mohammed, built upon his sayings and practices, and other traditions regarded as authoritative by the orthodox Mohammedans, although not part of the law, as set forth in the Koran. A great number of so-called "Traditions" were fabricated to uphold certain political and sectarian claims, but these were subsequently rejected. The six standard Sunni collections were all compiled under the Abbaside caliphs, and the earliest of them partly during the reign of Al Mamun. The four canonical collections of the Shiias are of later date and less trustworthy. See also MOHAMMEDANISM; SUNNITES.

SUNNITES, sün'ités, or SUNNI, the orthodox Mohammedans, who accept as authoritative the oral teachings of Mohammed, the deliveries of the orthodox imams, and the various traditions assumed to be traceable to those who had the confidence of the prophet, in addition to the Koran, which is received as law by Mohammedans of every sect. The Sunnites regard as heretics the Shiites (Shia) who do not accept the Sunni, as the body of oral tradition is regarded. While the animosity between the two great divisions of Islam, like that between Christians of different creeds, has vented itself, and among the more prejudiced still finds expression, in bloodshed and bitter persecution, there is a much more tolerant feeling in the present age than existed in the past, and Shiites occupy important places in the Turkish empire, which is almost universally Sunni. The Sunni contend that Mohammed never intended to establish any hereditary right in his descendants. See MOHAMMEDAN.

SUNNYSIDE. Washington Irving's estate at Irvington, N. Y. It is close to the Hudson River, about half a mile north of the Irvington railway station. It was bought in 1835 by Irving, who gave it the name of Sunnyside; at that time the estate contained 10 acres, later eight more acres were added. A small stone house was standing on the estate, known as Wolffert's Roost, which during the Revolutionary War was a station of the Dutch "water guards" who watched and constantly annoyed the British ships anchored in the river. It was an old-fashioned mansion, with many gables and according to Irving "as full of angles and corners as an old cocked hat." Its picturesque ness pleased the author's fancy, and while he had it enlarged and modernized under the direction of an artist, George Harvey, he was careful to keep its "old-time" appearance. English ivy grown from a slip brought from Melrose Abbey, was trained over the front, which it now completely covers. Though additions have been made to the house since Irving's time, the old part has not been materially changed, and maintains the same general appearance.

SUNSHINE STATE. The name given by statute to South Dakota, which is also known as the "Koyote State."

SUNSTONE, or aventurine feldspar, a variety of feldspar showing a beautiful golden schiller. This is due to the reflection of light from the surfaces of minute, tubular crystals of hematite or goethite, enclosed in the spar in parallel position. Under the microscope, or even with a pocket lens, these little crystals appear gorgeously iridescent. Sunstone from Tvedestrand, Norway, the finest known, is a reddish variety of olivine. A green microcline sunstone occurs in Pennsylvania.

SUNSTROKE, prostration due to exposure to intense external heat. Such exposure may be to the direct or indirect rays of a tropical sun or to the excessive heat of an engine room. In either case heat and physical exertion combine to bring about the results. A high degree of humidity of the atmosphere is one of the most important features, since this hinders free evaporation of fluid from the body which is one of the most important devices for cooling the body. Sunstroke was defined by Osler mentions that two instances are on record in the Bible and many of the ancients described it very well, confounding the severer forms with apoplexy. Two main types are seen—heat exhaustion and heat stroke. Other terms for heat stroke are isolation, thermic fever, coup de soleil.

Heat exhaustion is frequently seen among workmen who are exposed to the direct action of the sun. Bricklayers, drivers, farmers, etc., or firemen and stokers in large vessels, while in the midst of their work suffer from extreme prostration. There is great restlessness, muscular weakness, fainting spells and collapse, and often delirium. The surface of the body is usually cool and the temperature may be subnormal, 95° to 96° F., the pulse is small and rapid and unconsciousness rapidly develops. In heat stroke or thermic fever, the symptoms are quite different. Here marked physical exertion and direct exposure to the sun with high humidity are important factors—in addition some form of alcoholic drink is being taken, notably ale, beer or whisky. In the severe grades the patient may be suddenly struck down and die with rapid breathing, heart weakness and uncon-
SUPEREROGATION—SUPERIMPOSED DRAINAGE

Supererogation, performance of more than duty requires, for example, if one commits theft of a dollar and makes reparation of the wrong by giving back two dollars; or if one not only forgives those who injure him, but confers unmerited benefits upon them. The Anglican Church, in the 14th of the 39 Articles of Religion, expressly condemns the notion of works of supererogation as impious: “Voluntary works besides, over and above, God's Commandments, which they call Works of Supererogation, cannot be sought without arrogancy and impiety; for by them men do declare that they not only render unto God as much as they are bound to do, but that they do more for his sake than of bounden duty is required; whereas Christ saith plainly, When ye have done all that is commanded you, say, We are unprofitable servants.” Supererogation is not a term of theology in the Roman Catholic Church; but that Church teaches that good works done by the faithful in the state of grace are meritorious of eternal reward, and that merits of holy men redound, through the goodness of God, to the spiritual advantage of the whole Church. This doctrine differs not from that taught in the "Institution of a Christian Man," published by authority of convocation in 1537.

"I believe that whatsoever spiritual gift or treasure is given by God unto any one part or member of the mystical body of Christ, although the same be given particularly unto this member, and not unto another, yet shall they who are therein shall, by reason of that incomprehensible union and bond of charity which is between them, redound immediately unto the profit, edifying, and increase in Christ's Body of all other members particularly.

SUPERFÉTATION, a second conception and the formation of a fetus after a previous impregnation in the same female, whereby two fetuses coexist in the uterus. In such a case a woman may be delivered of a full-grown child and of an undeveloped embryo at the same time, the period of conception of each being presumed to be different; or a woman may be delivered of two living children, the one appearing much more developed than the other. In recorded cases women have given birth to twins, the one child being white and the other black, showing that each had a separate father and of a distinct race, and proving the possibility of a double conception. But far more typical cases of superfetation have been found. Such is that instance in which a woman, published by Eisenman of Strassburg, a woman was delivered of a second child 140 days after the first, both children being fully developed. In this case, therefore, the second child must have been conceived at a later and different period from the first; and the development of the second child must have been proceeding separately from that of the first, and after the latter was born. Still more remarkable cases of this kind have been recorded. The explanation of these curious cases has afforded a very intricate study and puzzle to obstetricians and physicians, as well as to those concerned with their medico-legal aspect, which sometimes bears directly upon questions of conjugal fidelity. As the subject is an important one, full elucidation is still a matter for obstetrical investigation; but there can be little doubt either of the actual occurrence of cases of superfetation, or of the great importance of the study of its phenomena.

SUPERHEATERS. See Locomotive.

SUPERIMPOSED DRAINAGE. When a stream flowing across a region cuts down and uncovers an old buried erosion surface the
drainage is said to be superimposed on that surface. For example, if any familiar region of hills and valleys should sink beneath the sea, and all the old surface be buried beneath sands and muds, a plain would result. If this plain would then emerge an extreme were off at start flowing over it, the new streams would pay no attention to the old buried topography, but would wander freely over the plain. As they cut down the region, they would uncover this old topography, and superimpose upon it. Such is much of the drainage in the glaciated regions, where glaciation has filled up the old valleys, and obliterated the old preglacial drainage.

SUPERIOR, Wis., city, port of entry, county-seat of Douglas County, on Lake Superior, and on the Northern Pacific, the Chicago, Saint Paul, Minneapolis and Omaha, the Duluth, South Shore and Atlantic, the Great Northern, the Minneapolis, Saint Paul, and Sault Sainte Marie, the Chicago, Milwaukee and Saint Paul and the Chicago and Northwestern railways, opposite Duluth. It shares with Duluth the commercial advantage of being the extreme western port of the Great Lake system of the United States. It has three connecting harbors, well sheltered and deep, making a combined length of 16 miles, and an extreme width of three miles. The city comprises the ports known as East, West, South and Old Superior. The climate is cool in summer and cold in winter. The chief manufacturing establishments are flour and lumber mills, iron and steel works, boiler works, windmill, factories, shipyards, bag factories, tractor factories, cooperage, chair factory, wagon and carriage works. Lath, shingles and other lumber products are also manufactured. It has also shipyards, coal docks capable of receiving 6,370,000 tons of coal, large grain elevators, a large dry-dock and a number of wholesale merchandise establishments. The government census gives the amount of capital invested in industries $70,000,000, and the annual value of the products $111,663,000. There is an extensive lake trade, and railroads furnish transportation for products sent to the interior. The principal public buildings are the government building, county court house, market building, Saint Francis Hospital, Saint Mary's Hospital, Woman's Christian Temperance Union Hospital, national and State banks, several business blocks and hotels. The educational institutions are a State normal school, the Finnish University, two business colleges, two high schools, public and parochial schools and two public libraries. The commission form of government is in operation. The port's foreign trade has become extensive in recent years, having now an annual volume of about $1,500,000, of which 80 per cent is in exports. The city's annual expenditure on various municipal activities is about $550,000, of which $200,000 is expended on schools, $100,000 on fire protection and $60,000 for police. Pop., about 62,500.

SUPERIOR, Lake, the largest expanse of fresh water in the world and the most westerly and most elevated of the great lakes of the Saint Lawrence basin; lat. 46° 30' to 49° N.; long. 84° 30' to 92° 20' W. It washes the shores of the State of Minnesota on the west, of Wisconsin and the northern peninsula of Michigan on the south and of Canada on the north and east. The greatest length, measured on a curve through its centre from east to west, is 420 miles; greatest breadth, 167 miles; circuit, about 1,750 miles; estimated area, 31,200 square miles; length above the feet 602 feet; approximate mean depth, 900 feet; maximum depth, 1,008 feet. It is of very irregular shape, widening out toward its centre and gradually narrowing, partly toward its eastern but much more toward its western end, to form an irregular crescent, with its convexity on the north and its concavity on the south. The northern shore is generally bold and elevated, presenting almost continuous ranges of cliffs, which vary in height from 300 to 1,500 feet; the southern shore is low and sandy, though occasionally interrupted by limestone ridges, the most remarkable of which, situated toward the eastern extremity, present a perpendicular wall 300 feet high, broken by numerous caverns and projections, and forming, under the name of the Pictured Rocks (q.v.), one of the greatest natural curiosities of the United States. The central portion of the lake is clear of islands, but there are smaller ones toward both the southern and the northern shores. In the former direction they are small, and, being insufficient to give shelter behind them, only increase the difficulties of navigation without contributing to form a single good harbor. On the north shore several of them, more especially the Isle Royale, are of considerable dimensions, and along with the indentations of the coast afford good shelter for vessels. The water of the lake, remarkable for its transparency, derives its supplies from a basin which is estimated at 54,000 square miles, and is drained by more than 200 streams. The water never freezes except in the shallow regions along shore. About 30 of the islands are of considerable size, but they are almost all impetuous torrents, interrupted by rocks and rapids. Superior discharges into Lake Huron, at the southeast end, by Saint Mary's River, which at Sault Sainte Marie descends 22 feet in three quarters of a mile, navigation being here carried on by means of two ship canals, one on the Canadian, the other on the United States side. Within the lake itself the only obstruction to its navigation are the violent gales to which it is subject. It is supplied with fish, principally trout, whitefish and sturgeon. There are a great number of fishing-stations. Large deposits of copper and iron are worked on the shores of the lake, especially on the southern shore along the northern coast of Michigan. The boundary line between Canada and the United States, in passing through Lake Superior, proceeds from the outlet nearly through its centre till it approaches Isle Royale, when it bends north so as to give that island entirely to the United States. It is carried south-southwest to its termination at the mouth of the Pigeon, in lat. 48° N. The chief towns on the shores of Lake Superior are Duluth, Minn., at the western extremity, with an excellent harbor; Houghton, Keweenaw Peninsula; Marquette, Mich.; Fort William, Ontario, also with a good harbor; and Port Arthur, Ontario. Consult Agassiz, 'Lake Superior: Its Physical Character, Vegetation and Animals' (Boston 1850) and Martin, 'Progressive Development of Resources in the Lake
SUPERNATURALISM — SUPERSTITION

SUPERNATURALISM, "above nature" or miraculous, in theology, the generally received belief that divine revelation is the sole and ultimate ground of the Christian religion; it is opposed to naturalism, the theory that what contain many truths these truths are only a reassertion of natural religion and therefore unnecessary; it is also opposed to rationalism (q.v.), which makes reason the supreme arbiter in all matters connected with revelation and the religion of Christ. Supernaturalism regards the Christian religion as an extraordinary phenomenon out of the circle of natural events and as communicating truths above the comprehension of human reason. Though the supernaturalist, no less than the rationalist, employs reason in matters of revelation, he does so only to search and judge those claims to a divine origin which Christianity puts forth; when he is once convinced that Christianity contains the correct teachings of God, it becomes his highest, his sole authority; called also supernaturalism.

SUPERPHOSPHATE FERTILIZERS. See FERTILIZERS.

SUPERSTITION, Popular. That which others believe and we do not, is classed as superstition. The religion of our friend, if differing radically from our own, seems to us a superstition. In the heart of nearly every human being, savage or civilized, exists a settled conviction that he dwells in the midst of an unseen world, peopled with beings of strange powers, who thwart the plans of his own life or assist him in his endeavors. Folklore, legends, ghost stories and witch tales were early in the 19th century regarded as mere fables, but in the light of modern science they are now as worthy of study as the surely not less indec31e recitals of Roman and Greek mythology. Every profession, trade and occupation has its peculiar superstitions lore. Even the farmer who studies the actions of animals will tell you what they portend concerning the weather and in many cases sensibly, too, for they build their homes and lay in their food through instinct given by Divine Providence with reference to the coming winter; they house themselves before the coming storm; their coats are heavy or light, as the winter shall be severe or otherwise, and they often give the farmer who watches them valuable indications concerning his crops. So to a greater or less extent man has followed the habit of the bird and the beast; he has been guided in all his acts by omens; he has often planted his crops, gathered his harvests, made his journeys, waged war, built his house and gone fishing and hunting according to imaginary signs and superstitious beliefs. Though many of the old omens and superstitions have passed into oblivion, there still exist among two or three race of people hundreds and thousands of popular beliefs and many of them seem destined to be extant as long as man exists. As indicative of the variety, peculiarity and unusual extent of present-day superstition, the following examples were collected from among the inhabitants and peoples of the world and now first collected will prove of undoubted interest alike to scientist, student and casual reader.

SUPERSTITIONS OF THE WORLD.

Africa.—The snake is held in superstitious reverence by some African natives, who once a year kill a cobra de capello and hang its skin to the branch of a tree, tail downward. Then all the children born during the last year are brought out and made to touch the skin. This, their parents think, puts them under the serpent's protection. The Kaffirs use the venom of the puff adder, to poison their arrows, and when they have any small quantity left they swallow it, having a theory that it will protect them from the effects of future bites. If they find a dead serpent they dress it in clothes and give it a superb funeral.

American Indian.—Various tribes of American Indians have a theory that every white deer has a "mad stone" in his stomach. They believe that the "Great Spirit" places this stone in the white deer's stomach, which is a "magnet" that a delicate animal may take in while eating grass. Feathers figure very prominently in the religious customs of most aborigines, and remarkably so in the Southwest. Among Navajos and Pueblos alike these plumage symbols are of the utmost efficacy for good or bad. They are part of almost every ceremonial of the infinite superstitions of these tribes. Any white or bright-hued plume is of good omen — good medicine, as the Indian would put it. The gay feathers of the parrot are particularly valuable. The Navajo Indian will not eat fish under any circumstances, and cherishes the belief that the use of such food will be followed by dreadful punishment.

Arabia.—Many Arabs, when overtaken by severe storms in the desert, cry out, "Iron! Iron!" which they think will propitiate the evil spirits who have raised the storm.

Arctic Regions.—The Eskimos believe in ghosts. Many also believe in the transmigration of the souls, that spirits return in animals, winds, rocks, ice and water, that they are evil, angry or good, as the elements may be favorable or unfavorable, and that they can be appeased by hoodoo rites if the performer is sufficiently versed in occult science. To chase away the wind they chant, drum and howl against it, build fires, shoot against it, and, as a last resort, fire the graves of the dead. Eclipses of the moon create the greatest consternation and almost paralyze the people with fear. When a child dies in some parts of Greenland, the natives bury a live dog with it, the dog to be used by the child as a guide to the other world. When questioned in regard to this peculiar superstition, they will only answer, "A dog can find his way anywhere."

Australia.—Some Australians say that Mit- yau, the moon, was a native cat, who fell in love with some one else's wife, and was driven away, to wander ever since. The natives of New Zealand tie the hands of their dead together and pull out their nails; this is for fear that the corpse may scratch its way out of the grave and become a vampire.

Bohemia.—The peasants of Bohemia have a queer superstition by which they think to rid themselves of the depredations of sparrows among their crops. A frequent charm is to
SUPERSTITION

plant, in the centre of the field, a stick or splinter of wood taken from the timber of which a coffin has been made, or to scatter about pieces of the coffin itself. It is also considered very effective to lay upon the threshold or window-sill of the barn or storehouse a human bone taken from a grave. In Bohemia the willow is said to be the tree on which Judas hanged himself, and it is supposed to have a special attraction for suicides.

Brazil.—Religious superstitions are common here. Once a year some churchmen dress up a figure to represent Judas (usually with red hair and sandy beard), and give it to the street arabs, who carry it about until it has been ridiculed by stones and other missiles and then burn it on the commons. In the same country the sailors dress a figure on certain feast days, subject it to all sorts of indignities, winding up the ceremony by hanging it at the yard-arm.

China.—Many Chinese guard their homes from witchcraft by suspending spectacles of herons' and cranes' legs on the door. At the new year the Cantonese clean out their houses and post near the doors a pair of scrolls made of red paper (the lucky color) bearing an inscription such as "Leaves of the moxa, like a banner, procure a hundred blessings." In China superstition is regarded with superstitious reverence and pride. In China, too, the old man of the moon is known as Yue-loa, and holds in his hands the reins of marriages among mortals. The future husband and wife are tied together by an invisible silken cord, which is only severed at death.

Cuba.—A belief very prevalent among the common people is that the rain water of May has peculiar beneficial qualities which that of no other time possesses. The moonlight in Cuba seems particularly objectionable, and strangers are warned not to go out in it with uncovered head, and not to go out in it at all if it can be avoided; it is thought that this light brings many evil effects and not under any circumstances will a superstitious Cuban sleep in its rays—he thinks that, among other things, it will draw his mouth to one side of his face. The hooting of an owl is taken as a very bad sign. The same as in urban life, they avoid trees of the kind which makes weird sounds near his home. This is supposed to break the spell, and it is not then inevitable that a member of the family shall meet death in the near future.

Egypt.—When Egypt was in the height of her power her people worshipped a black bull with a circular white spot in the exact centre of his forehead, and the advent of such a creature in any herd was the signal of wild demonstrations. Even as late as the time of Cleopatra such animals were shod with gold, and had their horns tipped with the same metal. Herodotus tells of a man who died with grief because he sold a cow that soon after became the mother of a black bull calf marked with the sacred white circle in his forehead. In modern times the Egyptian housewives mark their bread loaves with a cross, and housemaids insure a brisk kindling of a newly lit fire by making the same sacred sign over the grate. The sacred ibis of the Egyptians was supposed, from the color of its feathers to femalitve the light shade of the moon. It is said that its feathers would scare, and even kill, the crocodile. The bird was believed to deliver Egypt from winged and other serpents that came from Arabia. It was so deeply venerated that it entered the most sacred temples with impunity, and to kill one, even by accident, was a crime punishable with death. After death, its body was embalmed, and thousands of their remains have been found at Thebes, at Memphis and at other Egyptian cities.

England.—In England there existed, even so late as the 18th century, a superstitious belief that a man condemned to be hanged could escape that undesirable fate provided some compassionate woman came forward at the foot of the gallows and expressed her willingness to marry him. Superstition has always clung to the cricket. In Hull it is unlucky to kill them, and in Lancashire, it is said, they cut holes in the worsted stockings of those members of a family that kill them. It is a custom in many parts of England and the Continent to announce to the bees a death in the family, especially that of the master. Another superstition is that if the bees settle on the dead branch of a live tree a death will occur in the family within a year. In some places it is thought unlucky to sell them. They are given away for another gift. It was a popular superstition in Norfolk, that whatever you are doing the first time you hear the cuckoo, that you will do most frequently all the year. The English housewife will not sweep the dirt out of the front door, fearing to sweep away the fortune of the house. In the north of England, the peasantry do not favor naming a child after some respected ancestor; that departed worthy might not like it. In the same locality when the dairy maid churned for a long time without making butter, she would stir the cream with a twig of mountain ash and beat the cow with another, thus breaking the witch's spell. But to prevent accidents of this nature it has long been customary to make the churn staff of ash. For the same reason herd boys employ an ash twig for driving cattle. In England it was thought, and not many years ago, that oak trees were mysteriously protected, and many superstitions clung round the sacred tree. The hawk used to be hung up at the door of the house of May to guard the dwelling from witches. In Devonshire it was considered unlucky to plant a bed of lilies of the valley, as the person who did so would surely die in the course of the next 12 months.

Fiji Islands.—In the mountain country of the Fijis there is prevalent a superstition called by the natives "Tuka." The priests profess to possess an elixir of life, which, preventing decay or disease, insures to faithful disciples of this faith everlasting youth and vigor and a robust enjoyment of life. The natives who give their adherence to these priests (and this means the giving up of all they possess to them) are promised the life of immortal youth, the immediate resurrection of their ancestors, vengeance on all their enemies and oppressors, whose wives and property they should inherit, together with all the wealth of the white settlers, these latter being also promised to them for domestic slaves.

France.—Perhaps the most common of all French spread superstitions is the belief met with through all the south of France, that the
position of a drowned body may be discovered by a floating loaf of bread. Possibly the only scientific basis is that the loaf is apt to be carried by a current of water just as a body is. The French peasant's faith in fermented grape juice is truly beautiful. If his children are stricken with the measles he gives them beakers of wine, well sweetened with honey and highly spiced with pepper. For a severe cold he administers a quart of red wine and a melted tallow candle mixed. For scarlet or brain fever he gives eggs, white wine and soot, well beaten together. Not all their superstitions are curious—some are pathetic. A mother, for instance, often buries her dead child with its favorite toy, or her own beautiful hair in the coffin, that it may not feel quite alone. Along the sea coast, unless the waters are strewed with flowers by the fishermen's wives and daughters, there will be no fish to catch. A curious superstition which is current among the street gamins of Paris and the large cities of France, is that which makes it unlucky to pass a priest. To break the ill luck, the passer must immediately touch a piece of iron. Gamins carry in their pockets pieces of iron to touch, but none of them seem to know the wherefore.

Germany.—Throughout northern Germany and in the Low Countries the stork is held in beloved reverence, for the peasants believe that where the stork has its brood no fire can ever come. There is a German belief that any one who during his lifetime may have made cats his enemies, is certain to be accompanied to the grave amidst a storm of wind and rain. It is said to indicate good luck to have a spider spring his web downward toward you, but bad luck when he rises toward you. If one has a four-leaved clover, and carries it about on Christmas eve it is believed the owner has the power to see witches. In Germany the apple has been deemed potent against war. In Pomerania it is eaten on Easter morning as a preserver of peace. There is a Christmas night on Christmas night says a German proverb, "the wine ferments heavily in the barrels a good wine year is to follow."

Greece.—Before a Greek selects the day for his wedding he observes most minutely every omen, and with prayer and fasting and sacrifice, takes every precaution. The Grecian mother, before putting her child in its cradle, turns three times around before the fire while singing her favorite song, to ward off evil spirit.

Hawaii.—In the Hawaiian Islands the superstition that the Kanaka holds dearest is that concerning the power of the Kahuna, or native witch doctor. This power is almost limitless. If a native in any way offends a Kahuna he is in deadly fear that he will be condemned to die, and he immediately hunts up a Kahuna higher in rank than the one whom he has offended and asks to have the curse offset and neutralized.

Iceland.—The Icelanders have a superstition which they call "Skipimal," or the speaking of the sea. It is said that utterances can be heard forth from the motionless hulls of vessels; but few can understand the strange language.

India.—The natives of India have many curious beliefs and superstitions, some of which are essentially Oriental in their nature. The Hindus think it brings a person ill luck to be openly admired or praised, and if you should praise or even look too admiringly at a child the mother will hastily withdraw it from notice, and either beat it or say something disparaging of it in order to counteract your ill-omened admiration and avert the jealousies of the gods. In Burma it is rather a suspicious thing to give money for a charitable object. It is supposed to mean that the donor has been very wicked and is desirous to make amends. The Hindu troubled with a wart looks at the new moon, picks up a pinch of dust from beneath his left foot, rubs the wart with it—and when the moon goes so does the wart. In India one may observe the quasi sign of the cross which a Hindu makes should he chance to sneeze while performing his morning ablutions in the Ganges. Having touched his forehead, nose, ears, and cheeks with the tip of his finger, he recommences his prayers from the very beginning, and will do so as often as they are interrupted.

Ireland.—The Irish peasant is subject at all seasons to the sense of unexplained agencies. But at no other time is his helplessness against such fateful and inexorable agencies brought home to him as in Lent. Moreover at this time the auguries and omens assume an especially depressing complexion. Thus the "keen" of the Banshee, always an eerie presager of death, when it occurs during Lent has the gloomy significance of a double funeral. Peasant mothers in Ireland still carry their children to holy wells where the little ones are made to creep on hands and knees beating their infant breasts the while they pray and plead for Lenten mercy on their own and the manifold sins and wickedness of their fellows, and are bathed in the blessed water which is credited with a miraculous power of averting sickness and washing away sin. The ceremony is completed by tying to a tree in the neighborhood of these consecrated springs, a mass of colored rag as a thank-offering and propitiation to the particular patron saint who is believed to preside over the birth of the child and to hold its future in his keeping. The people in the south of Ireland are particularly fearful of the robin entering their homes, for they say that it is always a certain prognostic of severe snows and frosts.

I tale of Man.—One of the superstitious customs in Manxland is for the family on stormy nights to retire to rest at a very early hour, so that the good fairies may unobserved enter to find shelter and repose.

Italy.—In Italy the snake is invulnerable except during the full vintage of the moon, when the serpents are believed to become drunken on the vineyards, and may be slain. The slaying of one of these serpents, though, would be the calling down on the head of the slayer and his family forever some terrible plague. The superstition about snakes as guardians of buried treasure seems to be a favorite one with the Italian peasantry; for they believe that all snakes hover over where such treasures are. In Sicily the time honored superstition of the "Evil Eye" is still so widely spread throughout the island, even among the
upper causes, that no one who does not wear a charm is considered safe. A Venetian superstition is that the young girl across whose feet dirt is swept will never get married. The periwinkle has in Italy gained for itself the name of Death's flower, from the ancient custom of raising it for garlands when an infant died.

Japan.—Japanese sailors think it is a good omen to cross the bows of a foreign vessel and frequently they run considerable danger in order to do it. The Japanese have some curious ideas about their finger nails. One of them is to the effect that they must not be cut before starting on a journey, lest disgrace befall the person before he reaches his destination. Neither should they be cut at night, lest cat's claws should grow out. To throw nail parings into the fire is to invite some great calamity. If, while trimming the nails, a piece should fall into the fire, the person will soon die. They are superstitious about many flowers and that have none of them. Many favorites, as the orchid, gentian, daphne and azalia are utterly prohibited for felicitous occasions. There is also with them an aristocracy of flowers most sharply defined. The iris is of princely dignity, but because of its purple color it is not used for weddings. Some flowers in themselves are regarded as being ill omen. Such is the camellia, for instance, which is neglected because its red blossoms fall off whole in a manner which reminds them of decapitated heads.

Java.—When search is made for the body of a drowned person a live sheep is thrown into the water and is supposed to indicate the position of the body by sinking near it.

Mexico.—In Mexico the Indian carnation bears the name of the flower of the dead, and when a virgin dies it is customary for a young woman to carry a garland of flowers and sweet herbs in front of the coffin. The high priest of the ancient Mexicans gave aloë leaves, traced over with sacred characters, to people going among volcanoes, to protect them from the incident dangers.

Norway.—Norwegian sailors believe in the existence of a sea animal represented as having a fish body with the head of a man and the flowing rings of a boat. The merman sits upon the waves, plays the harp and, following the example of many of the Norse fishermen, wears a red cap. It is never seen more than once in seven years, and no matter how many vessels appear in its sight they all must inevitably perish. A curious custom is practised in Norway, where those in search of a drowned body row to and fro with a cock in their boat, expecting that the bird will crow when the boat reaches the spot where the corpse lies.

Persia.—In Persia the crowing of a cock is the sign of some event affecting the family, and the master of the house hastens to feel the bird's feet. If they are cold it is a premonition of death; but if they are warm the sign is propitious, and the master rejoices in coming good fortune.

Peru.—To procure rain the Peruvians used to lay a live fish in a vessel, half-drown it and give it nothing to eat till rain fell.

Philippine Islands.—In the interior moun-
tain districts the natives have gods innumerable; gods of the air, of the water, and in fact of everything imaginable. When sickness or death approaches, the witch or sorceress of the village is called in. An ox and a pig are killed; she places the reeking skull of the ox over her own head and works herself into a frenzy of invocation. The spirits of the dead receive special honors and sacrifices are made in their behalf. Many curious demons and hobgoblins abound in Philippine superstition, too numerous to be described in detail.

Poland.—Poland has a wealth of animal superstitions. The goat is there considered the best harbinger of luck, while the wolf, crow and pigeon are looked upon as unlucky. The skin of a cat worn on the chest is alleged to cure consumption.

Roumania.—The people of the gypsy tribe believe that a coin or shell or pebble carried by a person becomes imbued with his or her personality. For this reason the gypsies will not part with such an item. On the other hand, a dollar is sought after by Roumanian people throughout the world. In all lands this piece of money is held in high esteem for magical purposes. The gypsies believe that witches use egg shells to make plates, pots and dishes to feed from at their banquets.

Rumania.—Rumanian mothers tie red ribbons around the ankles of their children to preserve them from being harmed.

Russia.—Superstition has always found a place in Russia. The Russian General Skobelev would never ride in battle any other horse than a gray one, since it was on a gray horse that he fought his first battle (in the Russian war, 1863) and he believed that it would be fatal to him to change afterward. The primitive Russians place a certificate of character in a dead person's hands, which is to be given to Saint Peter at the gates of heaven.

Samoa.—The natives of Samoa, in order to secure the admission of a departed spirit to the joys of their paradise, wreath the head of the corpse with flowers, and offer, as the Chinese do, a baked pig to their god in the name of the departed.

Scotland.—In Scotland it is considered unlucky for the mother and her baby to go out of doors until the child is baptized; to be engaged with a ring containing either opals or emeralds; for lovers to give either a Bible as a present before marriage; to be married in a month where there is a letter a, such as May; also unlucky for any of the wedding guests to be dressed in green or black; a crepe bonnet or a band on a gentleman's hat. These ill omens entail lifelong misery to the newly married couple. A young woman who tries on a widow's cap that are son the Marrow is after marriage. It is unlucky to try on your bridal dress before the bridal day; to see your future husband on the day of the marriage until the ceremony. To bring flowering hawthorn into a house denotes a death in the family. In Scotland all salt cellars should be full on New Year's Day; otherwise the household having the empty cellars will suffer want during the ensuing year. In Scotland to pass a barefooted woman before going on board ship will result in scaring the fish. It is unlucky to hear the names Rosie, Fullie and White must never be on a fishing boat at the same time for
the combination will "hoodoo" the catch. Scotch sailors will not speak of a four-footed animal while on the ocean.

**Solomon Islands.**—The savages of these islands believe that the world is a coconuut shell of enormous dimensions, at the top of which is a single man, who communicates with the upper air, where human beings dwell. At the very bottom of this imaginary shell is a stem gradually tapering to a point which represents the beginning of all things. This point is a spirit or demon without human form, whose name is "Root of All Existence." By him the entire fabric of creation is sustained. In the interior of the coconuut shell, at its very bottom, lives a female demon. So narrow is the space into which she is crowded that she is obliged to sit forever with knee and chin touching. Her name is "The Very Beginning," and from her are sprung numerous spirits. They inhabit five different floors, into which the great coconuut shell is divided. From certain of these spirits mankind is descended. The islanders consider themselves as the only real men and women, were formerly accustomed to regard strangers as evil spirits in the guise of humanity, whom they killed when they could, offering them as sacrifices.

**Spain.**—The Spaniards never put the left foot first when stepping on board a vessel, for to do this will surely bring disaster. Spaniards, in the 16th century, believed that spiders indicated gold where they were found in abundance. In Spain the new born infant's face is swept with a pine bough to bring good luck.

**Sweden.**—In Sweden it is unlucky to kill a stork, a robin or a swallow. If one kills a wren he will break a bone before the year is out. It is also unlucky to kill a marten. Many animals possess the power of curing diseases. Three hairs taken from the "cross" of an ass, that is the mark running up the back and out at right angles over the shoulders, will cure whooping-cough, but the ass will die. Another sure cure for whooping-cough can be obtained by asking and following the advice of a man riding a piebald horse. Swedish sailors will not mention the name of the port for which they are bound.

**Switzerland.**—If a huntsman, on going out in the morning, sees a fox cross his path, or meets an old woman or friar, he immediately returns home again; as he is persuaded that, in the first instance, he will meet with no game, and in the other that he will shoot a man hidden in the leaves, or do some other irreparable mischief. In the Alps the mountaineers believe that if the cuckoo sings in the direction of the north, it will rain the next day; but if toward the south, the weather will be fine. In the Tyrol if a young girl look pale and sickly his parents suspect that the moon-rays must have found their way into her bedchamber.

**Turkey.**—In Turkey if a cat enters a chamber where a person is dying and manages to pass over his or her body before being driven from the room, both the dying person and the cat become vampires and live ever after by sucking the blood from living people. If one finds a piece of bread lying upon the ground he must pick it up, kiss it and carry it until he finds a hole into which it can be inserted. To step upon a piece of bread or to leave it lying upon the ground is one of the unpardonable sins and dooms the offender to the third hell, where he is perpetually gored by an ox that has but a single horn, and that in the centre of his forehead. The Turk is convinced that misfortune hovers where he sees a rose leaf fall to the ground, and many people pay particular attention to the flowers and leaves which are decaying, gathering them carefully to prevent them from dropping.

**United States.**—In Michigan a double cedar knot is carried in the pocket by some to cure rheumatism, and in New Hampshire a man may carry a gall from the stems of goldenrod for the same disease. Hickory nuts, the buckeye and its cousin, the horse chestnut, which brings good luck in New Jersey, are other foes to rheumatism in different localities. Some people wear a strange ring made of a potato with a hole bored through it for rheumatism and others carry a plain potato in the pocket. The charm is more potent if the potato has been stolen. According to a Maine belief, a nutmeg pierced and hung on a string around the neck prevents boils, croup and neuralgia. In some parts of Massachusetts the cows are believed to forecast the future, and if they "moop" after midnight it is a warning of approaching death in the family. Among the West Virginia mountaineers the crowing of the cock before the door tells of coming company. It is believed on Cape Cod and in many other districts along the New England coast that a sick man cannot die until the ebb tide begins to run. In New England the sailors carry as a talisman a bone taken from a living turtle, a pebble from a fishhawk's nest or a small bone from the head of a cod. In Connecticut the belief holds that beans and potatoes must be planted in the old of the moon to prevent them running to vines. In Texas some superstitious people carry a small bone from a fish's head, but the luck only comes after the charm has been lost. **SUPPÉ, soop-pë, Franz von,** Austrian opera composer: b. Spalato, Dalmatia, 18 April 1820; d. Vienna, 21 May 1895. His musical ability early manifested itself and when he was but 13 years old he composed a mass which was sung at the Franciscan church at Zara. His first opera, 'Sommerachtstraum,' appeared in 1844. His best known works are the operas 'Patitnitta' and 'Boccaccio,' and his overtures 'Poet and Peasant' and 'Morning, Noon and Night.' He was for many years Kapellmeister at Vienna.

**SUPPLE-JACK,** the popular name given to various strong twining shrubs, for example, certain West Indian species of *Paulinia* and *Serjania* which furnish walking-sticks; or *Cardiospermum grandiflorum* or the high-climbing shrubby *Berecithron* where they range in the southeastern United States and has tough, terete branches, oval leaves, small greenish flowers in panicles and oval purple drupes, which render it conspicuous in autumn. The supple-jacks of Australia are climbing, woody
SUPPLEMENTAL EDUCATION

varieties of Clematis aristata, and that of New Zealand is one of the largest brambles known (Rubus australis), reaching to the tops of the tallest trees. It is also called the New Zealand lawyer.

SUPPLEMENTAL EDUCATION. Definition.—Extension education is for every community and for everybody. It extends the opportunity for education to the whole body of the people, to the whole period of life and to all the vital interests of life.

Formal education may be said to include the systematic instruction which is imparted through personal contact with the student, whether by class-room work or lectures, when given under the direct guidance and supervision of trained instructors in schools, colleges, universities and similar institutions, as distinguished from knowledge acquired through the more informal methods of study whether or not allied with teaching institutions. These methods vary widely and range from the carefully organized study clubs of university extension courses to the entirely independent research work of single individuals in libraries, museums and similar educational institutions.

General Purpose.---Universities exist for two purposes: (1) To perpetuate and discover knowledge; (2) to disseminate that knowledge both in its academic and its practical results. Extension teaching furnishes a means of furthering knowledge in both these aspects, particularly the practical.

By instituting popular instruction in those practical, technical and cultural subjects over which universities tend perhaps unconsciously to exercise a monopoly those institutions can so influence public taste and intelligence as to contribute greatly to social progress. Nalder.

The chief object of extension work is to provide the best education possible at the lowest practicable cost for those who are unable to attend established educational institutions.

I. Systems.---University Extension.---History.—As early as 1831 some forms of university extension were in use in the United States in the work of the American National Lyceum, an organization which, though not associated with any educational institution, had a part in the wide spread of popular education. Lecture courses and debating clubs were begun in many city and country communities. In 1887 an address before the American Library Association on the subject of the English system of university extension aroused much interest, and as a result university extension work was begun in several cities in connection with the work of the city library. In 1889 Columbia University announced to the teachers in and near New York City the offer of certain elementary courses in science, to be given by means of classes outside the university. From this beginning university extension grew steadily as a power in popular education.

Purpose and Scope.—University extension provides a means for the acquirement of an education by those who for any reason are unable to attend the various colleges offering formal instruction. The courses are designed not only to assist such persons but also to supplement the regular work of such institutions by offering an opportunity for continued study to those who may have completed the formal courses.

Extension courses cover a wide range of subjects from those of a very elementary character to those which are of interest and benefit only to a highly educated and cultured class, the courses being adapted to the particular need to be met. In many instances it is difficult to make a clear line of distinction between university extension and the formal instruction of teaching institutions as exemplified in night schools and vocation schools.

Methods.---Extension service as carried on by the universities of this country varies widely in methods. In some institutions there is a separately organized extension faculty entirely distinct from the regular faculty, while in others extension work is conducted by the regularly organized faculties through the medium of the various departments. The former plan, which is relatively more expensive, provides for a highly specialized and intensive type of work, but the other secures co-ordination of effort by the various departments and co-operation on the part of the faculties that would otherwise be impossible.

1. Lectures and Classes.—More or less lecture work is offered in most of the institutions which do extension teaching. Several forms of such work are employed, in some cases all are used in the same institution while in other cases one form may represent the entire work of the institution along extension lines. One form of lecture work is the lecture class—often these classes are held on Saturdays or late in the afternoon of other days for the benefit of students who are fully occupied during the hours of the regular college classes. Frequently the lectures are given by members of the faculty, also by men engaged especially for the work and by local experts in particular lines. One of the chief developments in the establishment of local classes throughout the country has been in connection with engineering work. Classes have been formed in shops and factories, and short courses offered at a number of colleges and universities.

In California out of 300 classes held under the direction of the University of California in eight cities, more than 200 classes were in San Francisco alone, showing to what an extent extension service may contribute to the intellectual, industrial, social and commercial life of a great modern city.

The welfare work of university extension is based upon the theory that there is a large field of human interests, specifically social in their nature, which is not covered by any other public educational agency. Such interests are those of health, municipal affairs, a public forum, the music interests of a community and the promotion of the economic prosperity of the small town. Many other topics might be mentioned but these are typical and are the more easily organized and directed.

Extension work in home economics seeks to conserve the home through teaching and training the individuals who compose it. In the South there are nearly 1,000 women who are devoting their entire attention to Southern States. South Carolina has 45 county agents and 20 cotton mill villages organized for community improvement.

The extension work of normal schools includes all forms of educational activity carried
on by the normal schools among people who are not enrolled as resident students in the regularly organized classes. The extension work of these schools differs principally from that of the universities in that it lays special emphasis upon the study group or local class method, not upon correspondence work.

2. Study Clubs.—Some of the first steps in university extension were taken in the State of New York and it was the first State in this country to make university extension a part of its educational system. A special feature of the work was the development of the library system in all its branches. Through the traveling libraries division of the University of the State of New York, large collections of books were sent out as early as 1894 to university extension centers for the use of the study clubs formed in connection with the lectures. From this beginning has grown the present widespread use of the traveling libraries by hundreds of study clubs throughout the State.

The discussion of public questions of importance and interest has been encouraged and stimulated by the establishment of a service which supplies current information and data on live topics of the day. Package libraries consisting of books, pamphlets, clippings, and typewritten material on important social, economic and political questions, on the principles of debating and on the organization and conduct of debating societies are supplied freely to clubs, debating clubs and similar organizations. Local libraries co-operate by furnishing available material and in some instances, notably in the case of the New York State Library, the work is carried on directly under the jurisdiction of the library. This work has been very fully developed at the University of Wisconsin.

4. The Co-operative Plan.—The co-operative system has been defined as the co-ordination of theoretical and practical training in a progressive educational program. One of the reasons why the night school has not been able to cope with the problem of the illiterate of the adult worker with entire success is because it frequently does not connect his education with his work. Co-operation between school and factory whereby manufacturers agree with the school authorities to carry on apprenticeship courses in practical trades while the school gives generalized and special instruction, has already met with practical success. In the co-operative plan the students frequently work in pairs; while one is at the office, shop or laboratory, the other is at school, the two changing places weekly. Courses are properly called "co-operative" because they enlist the active co-operation of the outside practical world in directing some of the educational policies of the school. At the present time there is a growing tendency on the part of manufacturers, department store managers and others to conduct, often during business hours, classes for their employees along the lines of their specific forms of business or on general elementary subjects of education. Such schools are described more fully elsewhere under the subject of Corporation Schools.

Principal Present Day Agencies.—Of the many institutions conducting university extension courses at the present time among the most notable ones are the University of Wisconsin, University of Michigan and Columbia University.

1. Wisconsin.—The University of Wisconsin offers several plans of extension work for the benefit of persons who desire to study any subject as members of a club, class or study group and provides special guided outlines. Such co-operative study makes possible personal visits and class instruction from university professors and specialists. These plans are adapted to the needs of teachers' groups, women's clubs, labor unions, farmers, business men's associations, etc. The outlines which are provided carry the privilege of a lecture or series of lectures and of direction, guidance and assistance by the person who outlined the work. Because of this provision the studies are much more effective and interesting. There is a nominal charge for outlines with the attendant privileges and there is an increasing demand for this service. Recently a Chautauqua circuit has been established in the State for the purpose of providing instruction, inspiration and recreation.

Community institutes are held in various parts of the State to assist local communities to solve certain definite problems. These institutes are in charge of men specially trained in the economic and social problems common to small country communities.

The university in its extension work has free access to the Legislative Reference Department, the State Historical Library, the University Library and the City Library. The Wisconsin Free Library Commission and those in charge of the different libraries co-operate generously in this work. Bulletins are issued, bibliographies and study outlines are prepared and publications are supplied gratis in the State. The Wisconsin Civil Service Commission has co-operated with the university in educational work among State employees by means of conferences, talks, lectures and in various other ways.

2. New York City.—In New York city a plan is being followed of training persons already in the city public service through the co-operation of the College of the City of New York and the city government. In 1917 a thousand city employees were studying 1,300 courses in the evening classes. The College of the City of New York in cooperation with the board of education offers free extension courses in several centres to the teachers of the New York City schools.

3. Columbia University.—The extension teaching department of Columbia University offers many courses in subjects which form a part of the curriculum of Columbia College and in the more advanced branches of these subjects shares in the work for the higher degrees. Subordinate and subsidiary to this are the courses of secondary school grade for mature students who cannot return to ordinary schools of this type. The professional schools are represented in an increasing number of
SUPPLEMENTAL EDUCATION

courses so that students may pursue their studies in many special branches. In addition to the regular courses of the extension teaching department extramural courses in New York and in outlying cities are offered.

4. Other Agencies.—One that is attempting to reach working people along educational lines is the Young Men’s Christian Association. The subjects pursued in the Y. M. C. A. classes may be approximately grouped under six heads: (1) Commercial; (2) political; (3) industrial; (4) physical; (5) language and miscellaneous—music, first aid to the injured, etc.; (6) special schools, such as law, art, automobile, etc.

The Young Women’s Christian Association also has educational classes but comparatively little instruction is given in the regular high school subjects. The main effort is to help women who are self-supporting to become more efficient and to put within the reach of those who are not self-supporting the training which will assist them to a greater extent.

The University of Michigan endeavors to conduct its extension service as far as possible through established university channels. Its policy is to render through its extension division possible all the great labor of a public service commensurate with the equipment and facilities of the university. It is a condition that all extension lectures shall be free to the public and that they shall be so advertised. In one year 1,300 reprints were made for the 300 lectures offered. The total number of auditors reached throughout the State in the year was 71,500.

II. Home Education.—Definition.—There is no distinct line of demarcation between what is termed university extension and home education, but in general the former may be said to provide for the giving of instruction to groups or classes rather than to individuals. The work is conducted for the most part by teaching institutions by means of lectures and other methods which are not comprised within the lines of formal education. It is the extension of the teaching power of an institution beyond the boundaries of regular class-room work. Home education is that which can be acquired in the home independently of association in groups or classes. It embraces all means of obtaining knowledge which are individual in their nature as distinguished from education acquired through association with other individuals by means of classes, study clubs, lectures, etc. Correspondence schools, reading courses, libraries, museums and other similar sources all offer a means of securing an education without the formal instruction associated with class-room work.

Purpose.—A very large proportion of our people leave school before completing either the high school or grammar school course. Within a few years many of these people realize their educational limitations but because of age, hours of labor, financial condition or other cause it is impossible for them to resume a course of study in an educational institution. University extension courses and home education facilities are designed to meet the needs of such persons and of all who for any reason desire to continue their studies. The recent increase in the number of persons taking correspondence courses is the best testimony of the need of educational facilities to supplement those of our regular schools, colleges and universities. To obtain an education through individual effort without the personal guidance and inspiration of a teacher requires determination and perseverance, and those who take advantage of these supplementary educational opportunities show evidence of a real desire and serious purpose to acquire an education. There are certain benefits to be derived from formal education which cannot be obtained in any other way, but the serious and ambitious student may find in the United States ample opportunity to pursue his studies in his leisure hours at little or no expense.

Methods.—1. Libraries.—These are well termed “the people’s university” for they constitute the most universal, most accessible and most economical source for self-education. They are storehouses of knowledge which is made readily available to readers by modern methods of classification and indexing. Nearly all large libraries in this country are equipped with the latest and best bibliographical aids so that the student has every possible means of assistance at hand. Our libraries are frequented more and more frequently by people, increasingly frequented by those seeking information on all sorts of subjects. Ordinarily only such restraints with regard to the use of the books are imposed as are necessary to protect the rights of readers, and serious students are frequently granted special privileges. Within recent years all libraries have become much more liberal in their service to the public and have been transformed into active rather than passive educational institutions. “There is a sense in which the school may be looked upon as a fairer test of community opportunity than the library. The school is compulsory; it impresses people most during their most impressionable period. On the other hand the library reaches old as well as young. Once established it remains as a centre for the distribution of knowledge and hence of opportunity.”

2. Traveling libraries.—In some States library facilities, to a certain degree at least, are at the disposal of every citizen even though there may be no library in his local community. This distribution of books is accomplished by means of traveling libraries in some cases and in others by sending books by parcel post or express from a central public library or agency such as a State library or library commission. In the State of New York both methods are in use, the traveling libraries having been in operation since 1893. These traveling libraries are small collections of books, usually in units of 25 volumes, which are sent anywhere in the State without charge on condition that the books shall be for the use of the public. These libraries are intended primarily for communities without any free library facilities but under certain conditions they are sent also to small public libraries. There is a wide use of these libraries, aided by state agents and various organizations, and many “house libraries” of 10 volumes are borrowed by individuals. Institutions or individuals wanting only a few books for a month or less may procure them from the New York State Library by paying the return transportation charges. By means
of this library extension service any citizen of the State may secure books either free of all charge or at a merely nominal cost.

3. Reading Courses.—Reading courses on various topics are prepared and made available by libraries, schools, institutions, and governmental departments of education and by means of these guides to study, the individual is enabled to inform himself fully on the subjects covered by the courses.

The Home Education Department of the United States Bureau of Education work is carried on largely through personal correspondence and through the dissemination of reading courses. In 1917 there were 10 courses offered and approximately 100,000 copies of the printed outlines were distributed during the year. The bureau has been able to secure the co-operation of libraries and library commissions in bringing these courses to the attention of the public and in carrying on the work. More than 6,000 persons are now enrolled in the National Reading Circle and certificates are granted to persons completing the courses.

4. Museums.—The rise of the museum as a new force in town, city, state and nation is one of the educational factors of educational evolution. The growing museum influence which during the past quarter of a century has been especially remarkable throughout the cities of the United States is largely due to what may be called the new museum idea, namely that the museum is not a negative but a positive educational force and that it has teaching qualifications peculiar to itself. The most important function of a public museum is that of usefulness to the public in an educational way. With the great resources at their command museums are working out plans of various kinds for the definite instruction of the public, such as study rooms, illustrated lectures in the museum or elsewhere, tours of the museum under trained and competent guides, and loan collections.

One of the most interesting and important developments is the Children's museum, or Children's room which is one of the results of the growing conviction that the museum is a public institution which should meet the needs of all ages and classes of people.

5. Correspondence Courses.—Certain universities have especially emphasized correspondence-study work. At those institutions where this form of instruction has had the longest trial statistics show that the students who take advantage of the opportunities offered by these courses to do a certain portion of the work required for a degree cannot be classified among those who are seeking easy methods for gaining a degree. The students by and large are rising in the average grade of class-room student. The subjects offered are mainly cultural; those courses for which there has been the greatest demand include the languages, mathematics, history, education, political economy and technical subjects. A large number of biblical and theological courses are offered by some institutions.

Correspondence schools also play a large part in Home Education, but instruction by correspondence can never take the place of class instruction for it lacks the inspiration of personal contact. As a means of helping am-
correspondence study reaches literally every part of the world. Through the Correspondence Study Department the university offers a large number of the courses given in the classes of its different divisions, and all non-resident work for credit is conducted through this department. Each course is designed to be equivalent to the corresponding residence course and calls for an equal amount of work. No preliminary examination or proof of previous work is required of applicants for correspondence work. At the Pennsylvania State College correspondence courses are offered in agriculture, home economics and industrial education, free of charge to any citizen of the State. Students at the summer session are permitted to complete their work for certain subjects by correspondence at a nominal cost. At the University of Wisconsin 300 single courses are offered in 28 departmental lives and 70 of these courses are open to extension subjects. Each course is divided into units designated as assignments and each assignment represents six to eight hours of work. The instruction is carried on in three ways: by special letter notes, by correction of the exercises submitted, by personal letters and other assistance where special needs are otherwise met.

Education of Adults in Other Countries.

Schools for the education of adults originated in England through the Sunday School movement during the 18th century. The first adult school was opened in Nottingham in 1798 and has continued to the present day. The movement soon spread to other parts of the country and though providing secular instruction it was religious in its association. Parallel with these schools were classes in scientific and civic subjects. In 1831 the English government made pecuniary grants to evening schools. At the beginning of the 20th century out of every 1,000 of the population of England and Wales about 23 persons voluntarily attended some form of evening class on work days. Several agencies have been influential in the development of this movement — namely the Union, the National Home Reading Union, the Y. M. C. A., the Recreation Evening Schools Association and the Worker’s Educational Association.

England had in 1918 a new education bill which provides for national oversight, national direction and compulsory attendance of children from five to 14 years of age, for part time continuation schools for those between the ages of 14 and 18, for medical inspection, physical training and more than 30 other incidental aids to democratic education — this bill will revolutionize education in England.

University extension as a means of carrying higher education to adults has had an unparalleled success in England and the progress of the movement has been remarkable. Instituted by the University of Cambridge in 1827, adopted by Oxford in 1878, taken over by the reconstituted University of London in 1911 — these three universities are the world-wide acknowledgments of a priori merits of the movement. The original form of university extension teaching has not declined in England as it has in the United States. The characteristic features of the lecture system at local centres, with a class following the lecture and a final examination, have been maintained. Taking Oxford and Cambridge, 500,000 students have attended the courses given in nearly 40,000 lectures by over 200 lecturers and nearly 30,000 students have been examined.

One of the most far reaching educational results of the war of 1870, with its great lesson of the importance of national education, was the law of 1873 passed in Saxony making attendance at continuation schools compulsory for three years (that is up to 17 years of age) in that kingdom. The Saxon law appears to have been justified by the experience of a generation. There is no doubt that in this matter of continuation schools, as in so many other fields of social organization, the adoption of compulsion has been facilitated by the habituation of the working classes to compulsory military service.

Adult education forms an important part of the educational work of Denmark also. Children of ability who can pass the required examinations are sent from the communial schools to the middle school, gymnasia and university at State expense. Most other children go to work after five years at school but a fair percentage of them go to evening classes not only for technical training but also for higher education generally, and many attend University Extension lectures regularly for years after they leave school. A great social educational movement was started in Denmark in the late 80’s. The primary object of this movement which was organized and is still worked by students of the Copenhagen University, with the cordial help of the professors, is to draw together the diverse sections of the community, to weave bonds of friendly sympathy between them and to spread the light among even the lowest sections. Students hold night schools in the Copenhagen communal day schools and give lessons there gratis to all the working men and women who care to go. There are more than 3000 teachers and more than 2000 are taught. On Sunday are free popular lectures by students and professors to which the working classes flock in thousands. The Danes boast that in their country there is no ‘unenlightened class’ and they do so with good reason.”

William R. Watson,
Chief Educational Extension Division, State Department of Education, Albany, N. Y.

SUPPLEMENTARY PROCEEDINGS

are in the nature of a civil and equitable action whereby property of a judgment debtor may be reached, where said property cannot be taken under the usual process of execution; its object primarily is to discover the property of a judgment debtor which is subject to execution, and to learn if the debtor possesses or controls any property which is applicable to the satisfaction of the judgment. Any creditor who has reduced his claim to a judgment and issued execution thereon may institute supplementary proceedings, and the first creditor who does so and prosecutes the proceeding with due diligence obtains a prior lien over the property to which the creditor has a lien. Supplementary proceedings exist and are regulated according to the statutes in each State:
SUPPLICANTS—SUPPRATION.

SOME jurisdictions afford much the same remedy through other means. In the U.S., they do not allow the remedy against corporations. In some jurisdictions certain classes of property are exempt, as, for example, wages earned by the debtor within a specified time next before the institution of the proceedings, the period varying in different States. Orders for examination in supplementary proceedings are granted by a judge having jurisdiction according to the statutes under which the right to maintain the proceeding is derived and may be held before a judge or referee appointed for the purpose; this order must be served upon the person to be examined and it may be set aside on account of any defect but otherwise must be complied with. If, from the examination, it appears that the judgment debtor has in his possession or under his control property or money by which a judgment may be satisfied, the judge may, in his discretion, direct the debtor or person holding said property for him to deliver the property to a receiver for the purpose of applying same to the judgment. One who disregards or defies the orders of the judge in those proceedings is subject to punishment for contempt.

SUPPLICANTS, the name assumed by the Presbyterian petitioners against the introduction of Archbishop Laud's Service Book and the Book of Canons into the Church of Scotland; as their petition had no effect the Suppliants in 1638 signed the National Covenant and Confession of Faith, which year were ratified by the General Assembly: thereafter they were known as Covenanters (q.v.).

SUPPLY RAILWAYS. Under this designation are included all railways, except combat railways, that may be constructed or used for the supply of an army in the field. They may vary from a light portable track to a standard-gauge road. Their principal uses are to connect the army with its base; to connect permanent gun emplacements near the main line of resistance and for the movement of troops and supplies between bases and on the GOVERNING. In extreme cases a railway may have to be constructed to supply an advancing army when local conditions preclude other means of transportation.

Regardless of the gauge, the same underlying principles govern the construction of all such lines, and having a plan for the operation and maintenance of an existing line of railway, it is easy to adapt it to the requirements of a temporary line. The principal considerations that govern in planning such lines: (1) the amount of army supplies, troops and animals that must be handled; (2) the time that can be permitted for its construction; and (3) the amount of transportation necessary to place the railway supplies on the work which applies permanent roads. In the latter case the condition ordinarily necessitates a narrow-gauge railway for a supply railway in a country beyond the sea. Local conditions, such as a large supply of standard-gauge material and the ability to render advisable the building of a standard-gauge railway for operations from a friendly land base; but where conditions extremely favorable to a standard-gauge line do not exist, a narrow-gauge railway will probably be decided upon in the general case of supply railways. The weight of the materials and rolling stock is so much smaller, the bridges can be so much lighter, and the earth work is so much less than for a standard-gauge road that the narrow-gauge railway is decidedly easier and quicker to build.

In case an official report is desired by the commanding general before he decides whether or not to construct the line, the entire survey and the estimates must be finished before the report is made. This report is accompanied by maps and profiles showing the routes considered and the final location decided upon, and the reasons therefor. It also shows the approximate cost of material and of civilian labor, the amount and cost of rolling stock and other equipment, the capacity of the line when it is completed and the time that will be necessary to complete the work as desired. In case it has been definitely decided in advance to build the line, the cost and time are only considered in that they must be kept as low as practicable, and the survey need not be completed before construction work begins. See MILITARY RAILROADS.

EDWARD S. FARROW, Consulting Military and Civil Engineer.

SUPPOSITORY. A medicinal compound prepared in the form of a cone, space, or cylinder, for introduction into the rectum, urethra or vagina, there to be dissolved (melting gradually by the heat of the body) for the purpose intended, as action on inflamed mucous membrane, evacuation of the bowels, etc.

SUPPURATION. A morbid process in animal tissues which gives rise to the formation of pus. It is one of the destructive terminations of inflammatory action. The inflammatory leucocytes, instead of being dispersed (melting gradually by the heat of the body) for the purpose intended, as action on inflamed mucous membrane, evacuation of the bowels, etc.

The pus-globe shows more distinct trace of a membrane, and is frequently many-nucleated when treated with acid, a condition which Winkelmans regards as indicating a tendency to degenerate and break down. Many of the corpuscles of pus discharge no difference in character from the blood-leucocytes, having only single nuclei, showing the same amoeboïd movements, and being in fact obviously the same things both in structure and function. Suppurative is not, in most cases, wholly a destructive process, but serves to liberate the usual modes of repair. The result of the process of suppuration is thus twofold, being in part destructive and in part constructive. Suppuration in the interior of the body usually terminates in the formation of a suppurating ulcer, in which cases the matter is diffused through the interstices of the part, and is termed diffuse inflammation.
SUPRALAPSARIANS. See supra-lap-sa-ri-anz, those Calvinistic theologians who maintain the strict doctrines of Predestination, Election of Grace and Reproduction, namely, that the Creator for His own glory decreed the fall of man and the execution of sin into the world; and that the election of some to everlasting life and the damnation of others was made beyond (or before, supra) Adam's fall, and was in no way consequent on it or dependent upon it. See Predestination.

SUPRANATURALISM. See Supernaturalism.

SUPRARENAL CAPSULES. Two small, ductless glandular bodies situated at the front portion of the upper end of each kidney. They are generally classified with the spleen and similar structures as ductless glands. Each suprarenal capsule exhibits a yellowish color. That of the right kidney is somewhat of triangular shape, the left being of somewhat crescentic form. In some cases these bodies may be hardly recognizable on account of their minute size. Their average weight is from one to two drams. Each capsule is connected to its kidney by a pedicle of tissue only no vascular or other connections existing between the glands; and neither capsule has any outlet or excretory duct. They lie behind the peritoneum, or lining membrane of the abdomen, the front surface of the right suprarenal capsule being in contact with the under surface of the liver, the same surface of the left being in relation with the pancreas and spleen. The capsules derive their blood from the aortic, renal, and phrenic arteries, and return their blood by the suprarenal vein, which receives its blood from the net-work of the medullary portion, and also partly from the cortical substance of the organ. The nerves of the suprarenal capsules are numerous, and are branches of the solar and renal plexuses and of the phrenic and psoas trunks. The suprarenal capsules are present in all mammals, and are largest in Rodentia, and smallest, proportionally, in the whales, in which they are lobulated or divided into lobes. In birds of small size, and exist generally on the inner aspects of the kidneys. In sharks they exist as a single, long, lobular organ lying behind the kidneys; and in frogs and toads they appear as yellowish patches on the kidney. They are also lobular in sturgeons and other fishes, and in newts and Urodela generally. That these bodies may have some important function to discharge in connection with the blood-circulation of the embryo is a highly reasonable suggestion; but further than this general statement physiology cannot certainly proceed. Facts of much interest in connection with these bodies, however, have been observed in cases of Addison's disease (q.v.). The actual diseases to which these bodies are liable consists of hypertrophy or enlargement, atrophy or wasting, tuberculous degeneration, fatty disease and occasionally cancerous infiltration.

SUPREMACY. Royal, as a term in English law, is practically restricted to denote the authority of the Crown in matters ecclesiastical. After the abolition of the papal supremacy at the English Reformation, the royal supremacy was confirmed by various acts under Henry VIII and Elizabeth, all enforcing an oath of supremacy. The oath was taken by holders of public offices along with the oath of allegiance, and afterward with that of abjuration, until the three were consolidated in one. The revised oath of allegiance imposed upon members of Parliament, and the affirmation or reafirmation of royal supremacy in ecclesiastical matters. Supremacy acts were passed in 1534, 1559 and 1689.

SUPREME COURT OF THE DISTRICT OF COLUMBIA. See Court.

SUPREME COURT OF JUDICATURE. A legal tribunal in which are united all the higher courts of justice in England, exclusive of the appellate jurisdiction of the House of Lords and of the Privy Council. It dates from the Act of 1873. See Court.

SUPREME COURT OF THE UNITED STATES. The, is a cardinal feature of our Federal representative government, balancing and harmonizing all its parts, a tribunal which has received the general approval and admiration of foreign jurists and statesmen, and commands the universal respect and obedience of the people for whom it administers justice. The Federal Convention of 1787, which framed our Constitution and created this unique tribunal, was composed mostly of members of the legal profession, who had always in America been the chief nursery of statesmen; but Washington, the soldier, presided and Franklin, the philosopher, advised at every step. The members of the convention were undoubtedly chosen from the best qualified men that the country could furnish for the momentous work which was set before them, and their merits have been so universally recognized that it is not necessary to repeat any of the emphatic tributes which any Englishmen have paid to the results of their labors. Their work was finished in four months' secret session at Philadelphia, but most of them had been in training for it through 20 long years of trial and trouble. From 1765, the time of the passage of the Stamp Act, which was passed through both Houses of Parliament with little opposition, the colonists, and especially the lawyers of the Colonies, had been careful and earnest students of the principles of free government.

In 1774, having exhausted in vain all appeals to king and Parliament for a redress of their grievances, they sent delegates to a Continental Congress to deliberate on the state of public affairs; and in this Congress, which lasted for seven years, many of the future framers of the Constitution who were members of it found a most instructive school of statesmanship, and constantly devoted themselves to the social and political education of the colonists in matters of government and of public law and popular rights. In 1776, as the representative of the United States of America in General Congress assembled, appealing to the Supreme Judge of the world for the rectitude of their intentions, they did, "in the name and by the authority of the good people of the Colonies, solemnly publish and declare that these United Colonies are, and of right ought to be, free and independent States; that they are, and of right ought to be, absolved from all allegiance to the British Crown; and that all political connection between them and the State of Great Britain is, and ought to be, totally dissolved." They declared
that as free and independent States they have full power to levy war, conclude peace, contract alliances, establish commerce, and to do all other acts and things which independent States may of right do, and for the support of this declaration, with a firm reliance on the protection of Divine Providence, they mutually pledged to each other their lives, their fortunes and their sacred honor. From the hour of the Declaration, the men who made it, and all the other citizens of the Colonies, had to give re- marks and constant study to the whole science of government. As they proved able by force of arms to make good this declaration, the United Colonies became from its date a new nation, over which Congress, by general consent and acquiescence, exercised the powers of a general government, for all the purposes of the very serious exigency which had called it into existence. But it was a government by Congress only, with feeble and undefined powers, without an executive and without a judiciary. While the war lasted it barely sufficed, and afforded daily object lessons of its own defects and of what was required for a better government when better days should come.

The several States, being dissolved from the royal charters under which they had before practically managed their own affairs, adopted written constitutions, based in each case upon the sovereignty of the people, to take the place of the former dominion of Parliament. An epoch of constitution making set in, during which the principles of representative popular government were discussed and understood. Virginia, the largest of the States, the home of Washington, Jefferson, Madison and Monroe, who were to be four out of the first five Presidents of the United States, took a leading part. New Hampshire had already framed a temporary form of government "during," as they said, "the unhappy and unnatural contest with Great Britain." South Carolina and New Jersey had followed, but in the case of the former it was expressly declared that the Constitution established was "established until an accommodation of the unhappy differences between Great Britain and America could be obtained."

Massachusetts, in 1780, with the utmost pains and deliberation prepared and adopted a complete Constitution, in which the powers of government were carefully distributed, with the solemn declaration that neither the legislative, executive or judicial department should ever exercise the powers of either of the others "to the end that it may be a government of laws and not of men." During the war the other colonies were engaged in the same business of founding States upon the principles of civil and religious liberty, embodied in written constitutions. Rhode Island alone, founded by Roger Williams, the great apostle of toleration, having received from Charles II in 1603 a royal charter, preserved it until 1784 without adopting any written Constitution.

But it was not only in the individual States that the framers of our Constitution were in all those years gathering knowledge and experience, with a view to a consummation. From the very date of the Declaration, Congress, conscious of the inadequacy of its powers, even for the purposes of carrying on war and conducting foreign affairs, entered upon the novel and difficult task of arranging a scheme which should enable it more efficiently to conduct those affairs which were of common interest to all the people of the 13 States, and which no one of them, nor all of them individually could control. After two years they adopted an instrument of government by which they styled "Articles of Confederation and Perpetual Union," but it was not until March 1781 that the powers of Congress were enlarged by the final ratification of these articles by the delegates of all the States. But this attempted bond of union—a crude experiment in the formation of a national government—proved little better than a rope of sand, and utterly failed to accomplish the purposes intended. While the war lasted the tremendous pressure of their common danger and common distress kept the States together and made them obedient to the request of Congress which really had no power to command, but as soon as this external pressure was taken off, they fell apart, and each asserted its independent sovereignty. So jealous were the States, which had just escaped from the dominion of one central power, of anything which should seem to create dominion over them in another, that although upon paper they had laid many restraints upon their own actions, and conferred upon Congress extensive powers over their Federal affairs, they had carefully refrained from giving any sanction to those powers and from granting to Congress the means of compelling obedience to its enactments. The Articles provided for no Federal executive and for no judiciary department, although they authorized Congress to provide for the settlement of boundary disputes between States and to appoint courts of prize and for the trial of piracies and felonies on the high seas. Moreover, Congress could not of its own authority raise a dollar of money for revenue or a single man to recruit its armies. It could only make requisitions for men and money upon individual States, which met them or not as they found it convenient. Nor could it proceed at all in the exercise of the principal powers nominally conferred upon it until nine States assented to the same. One of the leading writers of the same thus describes the powers of Congress under this Constitution:

*By this political compact the United States in Congress assembled have exclusive power for the following purposes, without being able to execute one of them. They may make and conclude Treaties, but can only recommend the observance of them. They may appoint Ambassadors, but cannot defray even the expense of their tables. They may borrow money in their own name on the faith of the Union, but cannot pay a dollar. They may coin money, but they cannot purchase an ounce of bullion. They may make war and determine what number of troops are necessary, but cannot raise a single soldier. In short, they may declare everything, and do nothing.*

Judge Story says that, strong as this language is, it has no coloring beyond what the naked truth would justify. As John Adams himself wrote: "The Confederation appears to me to be little more than a shadow without the substance, and Congress a nugatory body, their ordinances being little attended to. Of course, under government, the public affairs drifted steadily and rapidly from bad to worse. Interest on the public debt could not be paid, nor the ordinary expenses of government be provided for. The treaties which had been made could not be carried out, and
foreign nations would not deal in the way of new treaties with the envows of a body which had no head and no power to perform what they should agree to in its behalf. Our external commerce was at the mercy of foreign nations, whose laws contrived for its destruction, Congress could do nothing to counteract. And worst of all, our domestic commerce, which between the citizens of one nation should be free and equal, was in the mercy of the cabals or selfishness of each individual State. There were many boundary disputes between States which threatened civil war. Federal laws were a dead letter, without Federal courts to expound and define their true meaning and operation, or an executive to see that they were properly executed. There was a general failure as yet to realize in actual enjoyment the advantages we had won by seven years of war, and everything seemed drifting toward bankruptcy, disunion and anarchy. But that was the whole power and resources of the evils which resulted from them, demanded the constant exercise of the best brains in all the States to understand and to remedy them, and opened a new school for all our statesmen in the study of constitutional government. When Washington had laid down his sword and surrendered his commission to Congress, after the signing of the treaty of peace which acknowledged the independence of the United States, he exhorted his countrymen by all they held dear to provide for the establishment of a strong and stable government as the only hope of retaining the liberties they had won; and from that hour until the Federal Constitution was made and ratified he and Hamilton, and Franklin and Madison, and all the other great statesmen who made it, or helped to secure its adoption, were engaged in the constant study of the principles of free government and in enforcing them upon the attention of their fellow citizens, so that they came to the performance of their great duties in the Federal Convention as graduates of the best practical school of Constitutional Law that the world has ever seen.

Their allotted task was to create a National Government which should reach, for its own proper purposes, by its own power, every man and every foot of territory in the whole United States, and should at the same time leave untouched and undiminished the complete control by each State of all its internal and domestic affairs—which should be entirely adequate without aid from the States, to govern the people effectively in all matters that involved the general interests of all, to deal with foreign nations and the people of the entire people behind it, in all the exigencies of peace and war, and to accomplish all this with the least possible vesting of arbitrary power in any department or officer of the new government. They differed in opinion and sentiment on many points, but all agreed in a supreme dread of arbitrary power, whether it should be exercised by the executive, the legislative or the judicial department, whether by a single man or by a majority of all, for they considered that the majority would have no restraints upon its power might become quite as dangerous as any other despot. They did not believe with my Lord Coke that absolute despotic power must in all governments reside somewhere. They carried this distrust of arbitrary power so far that they committed to the hands of the people, whom they regarded as the source of all political power, and deprived them of the right to consider any amendment of the Constitution until it should be proposed by a vote of two-thirds of both houses of Congress or by a Convention called by Congress, on the application of the legislatures of two-thirds of the States, and deprived them of the power of voting directly upon any amendment, which could only be ratified by the legislatures or conventions of three-fourths of the States.

In other words, the people of the United States who ordained the Constitution, deprived themselves of the power to modify it by the direct vote of a majority or two-thirds or even three-quarters of their own numbers, whether that number should be 3,000,000 or 80,000,000. They must act deliberately and indirectly through Congresses, legislatures, conventions and primary elections. Truly a rare instance of political self-restraint at the hands of a popular government. One of the best definitions of the objects of such government is contained in the preamble of the Constitution:

"We, the People of the United States, in order to form a more perfect Union, establish justice, insure domestic tranquility, provide for the common defence, promote the general welfare and secure the blessings of liberty to ourselves and our posterity, do ordain and establish this Constitution for the United States of America."

It was to "establish justice" for the people of the United States that the Federal judiciary, with the Supreme Court as its head, was created. It forms the balance wheel by which the affairs of the nation and its relation to the States are kept in working order, and is itself held in check by the power of the President to appoint its members as vacancies may occur, and by the power of Congress to impeach them for misconduct, to regulate the measure of its appellate jurisdiction and to increase or diminish its numbers. The permanent stability of the judicial power is assured by its being imbedded in the Constitution, with a representative body, find with that of the executive and legislative departments, by the extreme difficulty in the way of any amendment that would impair it, and by the universal conviction which the experience of a century has produced, that its continued existence with the full enjoyment of its present functions is absolutely essential to the successful working of our scheme of popular representative government.

The great achievement of the framers of the Constitution, was so to distribute the powers of government between the States and the Nation, as to give the latter supreme control over all subjects that concerned the general interests of all, and reserve to each of the former exclusive control over local affairs which concerned only its own territory, and do this in such a way that the State and Federal administrations should not clash in actual operation. They knew the importance of a distribution of the powers of government between the three great departments. They created a Congress on which they conferred legislative powers over 18 enumerated subjects,
necessarily involving the general interests of the people of all the States and essential to national sovereignty, including the levying and collection of taxes for Federal purposes, the borrowing of money, the regulation of commerce with foreign nations and among the several States, the coining of money, declaring war, raising and supporting armies, and maintaining a navy. They placed such limits upon the exercise by Congress of legislative power as should prevent its interference with legitimate local administration by the States, or with the fundamental rights of the citizens, and put such prohibitions upon the legislative power of the States as should prevent their interference with the general powers and functions of the Federal government. They vested the executive power of the Federal government in the President, who was made commander-in-chief of the army and navy and of the militia of the States when called into the service of the United States. He was granted power to proclaim reprisals against a State, to make treaties, provided two-thirds of the Senate concur, to have a veto power over acts of Congress, which could be overridden only by a vote of two-thirds on reconsideration. He was also to nominate, with the advice and consent of the Senate, ambassadors, judges and all the principal officers of the United States, to recommend to the consideration of Congress such measures as he should judge necessary and proper, to commission all officers of the United States, and to take care that the laws should be faithfully executed.

And, finally, to secure the absolute supremacy of the Federal government over all matters of Federal cognizance, it was expressly provided that "this Constitution and the laws of the United States, which shall be passed in pursuance thereof, and all treaties made under the authority of the United States, shall be the supreme law of the land, and the judges of every State shall be bound thereby, anything in the Constitution or laws of any State to the contrary notwithstanding." This making the Federal Constitution and treaties made, and laws of Congress passed under its authority, the supreme law of the land is the key of our dual system of government, as the sovereignty of Parliament is the key of the British Constitution. But the Federal government, though supreme within the limits prescribed, is not omnipotent; it must keep within those limits. By the 10th amendment, passed immediately after the adoption of the Constitution, to prevent Congress from meddling with the domestic concerns of the States, or exercising powers not granted to them, it was expressly provided that the powers not delegated to the United States by the Constitution, nor prohibited by it to the States, are reserved to the States respectively, or to the people.

Thus the people of the United States created for themselves two separate and distinct governments, each of the people, by the people, and for the people. The federal government, independent and exclusive of the other within its own scope and sphere, and each able, without aid from the other, to reach for its own purposes, by its own authority, every person and every foot of land within its territory, and to keep as it sees fit, or to live under other forms of government, this dual system has worked very simply, smoothly, and harmoniously from the beginning until now, except for the single occasion when the terrible question of slavery proved to be too much for all the departments of government combined, and could only be settled by our long years of Civil War. But how has this marvelous result been accomplished? How has it been possible for these two governments, each of prescribed and limited powers, and each department of both similarly defined, to act independently and at the same time harmoniously over the same people? By what magical force has each power, State and Federal, been kept within its own limits? What has prevented constant and hopeless conflict between State functions and officials, and Federal functions and officials, between State and Nation, and between State and State, originally 13 in number and now 48? How has it been possible to secure the due protection of the law to the citizens of one State in each of the other States, and the rights of aliens against a State, to make treaties in any State, and how has the faith of treaties been preserved in every locality? These, and a thousand other similar questions and doubts as to the successful working of our system, are answered by pointing to the Supreme Court created by the Constitution, and to the Federal courts inferior to it created by Congress, in which the judicial power of the United States is vested, a power which, as has been said, is co-ordinate and co-extensive with the executive and legislative. Over whatever region Congress may attempt to legislate or the President to execute its laws, there the judicial power extends, to pass, if need be, upon the legality of their acts and the validity of their laws. The Constitution, and each of its provisions, is supreme over President, Congress, Courts and States, and the valid laws of Congress, and treaties made under the authority of the United States, are the supreme law of the land for all its people, and for the courts, legislatures, and governors of each State. The Supreme Court is the final judge of the validity of all laws passed by Congress or by the legislatures of each of the 48 States, when brought to the test of the Constitution of the United States, and of the governors or State. The Supreme Court brings to the same test. It and the Federal courts inferior to it furnish the vehicle by which the judicial power of the United States is carried into the whole of its vast territory, to administer justice within the limits prescribed to it, to enforce the Federal laws and to punish offenders against them.

The third article of the Constitution is marvelously brief and simple. The judges, according to that good old rule which has worked so well in England since the days of William and Mary, are to hold their offices during good behavior, and can only be removed by impeachment, and their compensation shall not be diminished during their continuance in office. The Supreme Court has original jurisdiction only in cases arising under the Constitution, and laws,ta their enforcement, and in cases of bills of attainder and ex Künt ins, and in those in which a State shall be a party. The first branch of this original power has seldom been invoked, but over and over again a great State has been brought to its test, to peace, and to boundary disputes, always the most dangerous
to the peace of adjoining States, and in each instance its decree has been submitted to with implicit obedience—a most unique judicial power, and a most convincing example to persuaded persons to settle controversies with each other at the highest level ever attained in the progress of representative government.  

Toqueville says: "In the nations of Europe the courts of justice are only called upon to try the controversies of private individuals, but the Supreme Court of the United States summons sovereign powers to its bar." John Stuart Mill declares it to be "the first example of what is now one of the most prominent wants of civilized society, a real international tribunal." In all other matters the jurisdiction of the United States exists only apppellate. The judicial power extends only to cases as they arise between party and party, and in the Supreme Court as they come to it mostly by appeal from the inferior Federal courts, or by writ of error to the State courts. The courts of the United States exercise no supervision over, or interference with the President or Congress, or the legislatures of the States. They have no veto power. They do not act in wait for acts of Congress, to strangle them at their birth. They have no jurisdiction to pronounce any statute, either of a State or of the United States, void because irreconcilable with the Constitution, except as they are called upon to adjudge the legal rights of litigants in actual controversies. They simply pass upon the rights of parties as they come before them, and if a provision of the Constitution, or of a Federal statute, or a treaty is invoked for or against a right claimed or denied, they interpret the Constitution, the law, or the treaty, and determine the right. In this way, and in this way only if an act of Congress or of a State legislature is claimed to be invalid, or an official act is claimed to be illegal under the Constitution of the United States, and the decision of that question is vital and necessary to determine the jurisdictionary duty of interpretation, and declare the validity or invalidity of the act, and so determine the right between the parties before them in that particular case, and for no other purpose, and this may happen months or years after the enactment of the statute.

The Supreme Court performs no duties except judicial duties. So, when in 1794 President Washington requested the opinions of the judges on the construction of the treaty with France of 1788, they declined to comply, and when an early Congress enacted that certain pension claims should be considered and passed upon by the Federal courts, the Supreme Court upheld them in refusing to act under it, upon the ground that the power proposed to be conferred was not judicial power within the meaning of the Constitution. Nor will the court give a hearing to a fictitious or collusive case, contrived to raise a question as to the validity of a statute, or in any way with the intent prescribed to it of exercising judicial power. The Federal judiciary has steadily refrained from exercising any political power, which belongs exclusively to Congress and the President, and so it has been brought into no collision with the other departments. It will not even indulge in discussions, or express opinions upon purely political questions, lest perhaps to induce it to interfere either to restrain or compel the President in the exercise of his power to see that the laws are faithfully executed have failed. In the case of foreign nations, as well as in that of the sovereign States of the Union, the government acknowledged by the President, or by the President and Congress, is always recognized by the Supreme Court. In all such questions as are purely political it holds itself bound by the acts of the other departments. So the question whether and upon what conditions aliens shall be excluded from the United States, belonging to the political departments of the government, the court refused to express any opinion upon the constitutionality of the measures enacted by Congress in the exercise of the powers confided to it by the Constitution over that subject. Thus it constantly sets the example to each of the other departments of the government of minding its own business, and keeping strictly within its assigned province. But, careful as the judges are to confine the exercise of the Federal judicial power to cases as they arise, that power does extend to "all cases of law and equity arising under the Constitution, the laws of the United States, and treaties made under their authority," to all cases affecting ambassadors, other public ministers and consuls, and to all cases of admiralty and maritime jurisdiction; and whenever any such case does come before the Supreme Court it must take cognizance of it, and it cannot shrink, and never has shrunk, from determining the question of private right so arising. It is under these clauses that its unique and peculiar function of testing the validity of State laws and constitutions and of Federal statutes, and the legality of the acts of State and Federal officers arises.

The remainder of the Federal judicial power depends wholly upon the character of the parties to the controversy. It extends to controversies between which the United States is a party. This enables the Federal courts to enforce the acts of Congress, civil and criminal, against all persons within the realm; to controversies between two or more States, the purpose of which has already been indicated, as making the Supreme Court the arbitrator and peacemaker between sovereign States; to controversies between a State and citizens of another State, between citizens of different States, between citizens of the same State, in cases arising under grants of different States, and between a State, or the citizens thereof, and foreign States, citizens, or subjects. It was wisely concluded that in all such cases justice would be safer and surer, against State or local interest, prejudice or passion, in courts representing and vested with the authority of the whole nation, than in the courts of the State of an interested party, and that foreigners especially should have the right to have their causes heard and decided by national tribunals. These clauses, which make jurisdiction dependent upon the character of the parties, have been a prolific source of litigation in the Federal courts, have
opened to them the entire field of law and equity; have extended their adjudications to the whole body of jurisprudence, and have given to the decisions of the Supreme Court, by reason of the weight and force of character of the court and its members, a commanding authority with the States in general, and the particular institutions with foreign tribunals. But in this department of its functions the Supreme Court does not differ, in the scope of its powers and duties, from the courts of last resort of other nations, and its distinctive and peculiar character is not involved. The power of the court to declare State and Federal statutes, and the acts of the National and State executive officers invalid, as being in violation of the Constitution of the United States, naturally attracts the attention of foreign observers.

In the 130 years of its existence the court has pronounced 33 acts of Congress, and more than 225 State statutes, to be in conflict with the Federal Constitution, and therefore invalid, and in each instance there has been complete and final decision. This is not that instead of being a disturbing element, the exercise of this power confirms the peaceful relation between the States and the Nation, and between the States as among themselves, protects foreign nations from the breach of treaties, and conserves the rights of property and contract, and the fundamental rights of personal liberty. The Constitution provides that "no State shall pass any law impairing the obligation of contracts," and the aid of the court has often been invoked for protection against the attempts of States to violate this prohibition. The framers of the Constitution believed, and the people of the United States, in view of the successful operation of this prohibition for more than a century, believe that the States ought not to be permitted to intervene between the parties to a contract, to destroy or impair the binding force of terms by which they have agreed to be bound, and that such intervention is contrary to the principles of popular government, that in the days that tried men's souls before the adoption of the Federal Constitution many attempts had been made by States to intervene for this purpose, which doubtless led to the adoption of this clause.

Mr. Hamilton, in the Federalist classing such laws asillops, and ex post facto laws, which are prohibited by the same clause, says:

"Laws impairing the obligation of contracts are contrary to the first principles of the social compact, and to every principle of sound legislation. They are prohibited by the spirit and scope of the State constitutions. Our own experience has taught us, nevertheless, that additional fences against such dangers ought not to be neglected. Very properly, therefore, have the Convention added this constitutional provision for the security of personal liberty and private rights. And I am much deceived if they have not, in so doing, as faithfully consulted the genuine sentiments as the undoubted interests of their constituents. The sober people of America are wary of the fluctuating policy which has directed the public councils. They have seen with regret and indignation that sudden changes and legislative interferences in cases affecting personal rights, become jobs in the hands of enterprising speculators, and spoils to the more ambitious and less informed part of the community. They have seen, too, that one legislative interference is but the first link in a long chain of further interferences, every subsequent interference not being naturally produced by the effects of the preceding. They even believe, therefore, that some thorough reforming and winding which will banish speculations on public measures, inspire a general prudence and industry, and give a regular course to the business of society."

In the celebrated Dartmouth College case the protection of this clause was invoked by the trustees of the college, to recover its property from a person who held it for new trustees under the authority of a law of the State of New Hampshire. In 1769, King George III by a royal charter of privilege incorporated the college named "The Trustees of Dartmouth College," granting to them and their successors the usual corporate privileges and powers, and authorizing the trustees who were to govern the college to fill up all vacancies which may be created in their own bodies. The appointment by the founder, who had already established the college, was for a charter to incorporate a religious and literary institution, and stated that large contributions had been made for the object, which would be conferred upon the corporation as soon as it was created, and on the faith of the charter the property was conveyed to it. After the Revolution (in 1816), the legislature of New Hampshire passed an act increasing the number of trustees to 21, giving the legislature the additional power of control over the governor of the State, and creating a board of overseers with power to inspect and control the most important acts of the trustees. Admitting that the provision of the Constitution embraced only contracts which respect property or some object of value, and which confer rights which may be asserted in a court of justice, and did not refer to grants of political power or to acts creating institutions to be employed in the administration of government or of public property, or in which the State as a government was alone interested, and the court mature consideration reached the conclusion, that the charter was a contract which secured to the trustees the property and control of the college—a contract made upon valuable consideration—for the security and disposition of property, and on the faith of which real and personal property had been conveyed to the institution, and, therefore, a contract, the obligation of which could be impaired without a violation of the Constitution of the United States. It held that the statute of New Hampshire did impair it, and rendered judgment restoring the property and control of the college to the trustees who represented the founder. The opinions of Chief Justice Marshall and Judge Story are masterpieces of judicial reasoning, and the principles laid down by them have ever since prevailed. In 56 cases decided by the court, acts of State legislatures have been declared invalid in accordance with these principles, because they impaired the obligation of contracts, and it is not too much to say that, instead of having a disturbing or disintegrating effect upon civil society, these decisions have done more than any other single cause to inculcate a reverence for the law, and for the sanctity of the right of private property, which is one of the chief objects of free government.

It is true that the constitutional prohibition against laws impairing the obligation of contracts does not expressly apply to Congress. In the convention, Mr. Gerry, a prominent delegate from Massachusetts, made a motion that Congress ought to be laid under the like pro-
hibitation, but found no seconder. But in the amendments which were proposed by Congress at its first session, almost as conditions on which many of the States had adopted it and which were quietly ratified, other restraints were laid upon Congress which had the like effect. It was expressly declared that no person shall be deprived of life, liberty or property without due process of law, nor shall private property be taken for public use without just compensation. No matter what the emergency, it cannot violate these fundamental principles of personal rights. The court has held that the United States cannot, any more than a State, interfere with private rights except for legitimate governmental purposes, that they are as much bound by their contracts as are individuals, that if they repudiate their obligations it is as much repudiation, with all the wrong and reproach that term implies, as it would be if the repudiator had been a State, a municipality or a citizen. But strict and earnest as the court has been in enforcing its constitutional prohibition against laws impairing the obligation of contracts, it has been remiss in recognizing and giving full force and effect to the statutes of other nations which imposed no such prohibition on the law-making power.

The Canada Southern Railway Company, under its charter granted by the Dominion of Canada, had issued its bonds at a high rate of interest, and had sold them in New York to citizens of the United States, but getting into difficulties the company devised a scheme of arrangement, which was enacted by the Dominion Parliament, by which the interest on the bonds outstanding was scaled down to a lower rate without the consent of the bondholders, a clear case of impairing the obligation of a contract. The bondholders appealed to the Supreme Court, which held that the arrangement Act was valid in Canada, and bound non-asserting bondholders there by force of the scheme; that as it did have that effect in Canada, the courts of the United States should give it the same effect, even as against citizens of the United States whose rights accrued in the United States before its passage; that there was no constitutional prohibition in Canada against the passing of laws impairing the obligation of contracts, and that, under these circumstances, the true spirit of international comity required that schemes of this character, legalized at home, should be recognized in other countries.

The clause of the Constitution giving Congress the power to regulate commerce with foreign nations and between the States, has been another fruitful source of business in the Supreme Court in the way of testing the validity of State laws. At the outset of steam navigation, the State of New York undertook to reward Robert Fulton for his invention and enterprise by an act giving him the monopoly of navigating by fire or steam all the waters within the jurisdiction of the State. Under this act the assignee of Fulton had commenced running a line of boats between certain ports of New York and New Jersey. Obtaining from the State courts of New York an injunction to restrain the owners of an opposition line of boats, put on between the same ports, from entering the waters of New York State with their boats. But the Supreme Court held, upon appeal, that the New York enactment was a conflict with the power of Congress to regulate commerce, and with its acts in respect to commerce, and upon this ground vacated the injunction and established the right of all vessels to enter the port of New York under the authority of Congress. It was held that by virtue of the clause referring to Congress had exclusive authority to regulate commerce in all its forms in all the navigable waters of the United States, their bays, rivers and harbors, and to make navigation free to all without and restraint or interference from any State legislature. By a long series of decisions that followed under the commerce clause the court, with inflexible firmness and far-reaching sagacity, established the absolute supremacy of the nation over the whole subject of commerce, navigation, travel and intercourse between the States, which went far to strengthen the power of the Union. At the same time they secured to the citizens of every State the full enjoyment of the privileges and immunities of citizens in all the other States, and also that absolute freedom of internal trade throughout the country which has so vastly promoted the prosperity of the people.

The influence of the court in maintaining the faith of treaties has been powerful and far reaching. By the treaty of peace with Great Britain, in 1783, it was agreed that British creditors should meet with no lawful impediments in the collection of their claims; and the Constitution said that treaties, like laws, made under its authority, should be the supreme law of the land. Various attempts had been made by several States, before the adoption of the Constitution, to impede or prevent the collection of such claims. The subject provoked bitter and exciting controversies, but the court, against the contention of John Marshall himself, then at the bar, held that the treaty was supreme, and equal in its effect to the Constitution itself, in overruling all State laws upon the subject, and that its words were as strong as the will of man could devise to override all obstacles directed against the recovery of such debts. Of course, any such law passed by a State after the treaty contrary to its terms would be void.

Perhaps the most striking illustration of the power of the court to declare acts of Congress itself invalid, as contrary to the Constitution, was the celebrated Income Tax (q.v.) case. Congress in 1894 had passed a General Revenue Law, certain sections of which imposed an income tax upon incomes exceeding a certain amount named. This tax was levied indiscriminately upon all incomes alike, from whatever source derived, whether from the rents of real estate, the income of invested personal property or from earnings. But the Constitution had ordained that direct taxes should be apportioned among the several States according to the numbers of their respective populations, in contradistinction to duties, imposts and excises, which should be uniform throughout the United States. But the Act was rendered invalid by those who challenged the validity of the law, that taxes on rent, and taxes on
the income derived from invested personal property, were direct taxes within the meaning of the Constitution, and that instead of being levied uniformly, man for man, throughout the United States the relative proportion of wealth apportioned among the several States according to population. The difference was very considerable and substantial. The effect of the act, if sustained, would be to throw the principal burden of the tax upon a few large States, in which the relative proportion of wealth was in excess of the relative proportion of population, and to exempt the other States proportionally from their constitutional share of the tax. The opponents of the income tax also insisted that any such apportionment, which should arise from its being apportioned among the States according to population, was an inequality contemplated by the framers of the Constitution, and was intended to prevent an attack upon accumulated property by mere force of numbers. The court, against vehement and powerful opposition at the bar, and from a formidable minority of the members of the court itself, took this view, and declared the tax to have been laid unconstitutionally, so far as it affected income in personal property. And as the invalid portions constituted so large a proportion of the whole income tax levied by the act, that Congress could not be deemed to have intended to impose the rest without them, it further adjudged that all the tax provisions of the act, which constituted a single and entire scheme, must be held void. There were some popular protests against the decision, and direful prophecies that it would disable the nation in future emergencies from raising the revenue needed, but no such results have yet appeared. Congress, in its subsequent enactments, has conformed to the decision, and when the war with Spain came on, and an immensely enlarged revenue was needed at once, it found no difficulty in imposing taxes constitutionally and so successfully that, the year after the war closed, the Treasury was found to be burdened with so great a surplus that the entire body of war taxes had to be repealed at once. The same case contains a fine example of the power of the court to protect the States in the exercise of their legitimate power to manage their own affairs from interference by the Federal government. The income tax was levied also upon income derived from the interest upon bonds issued by municipal corporations, which were but civil divisions of the States, and the court held that as a tax upon the income of municipal bonds tended to cripple the power of the local authorities to raise money for the purposes of local government, it was not within the power of the Federal government to impose it, any more than it would be constitutional for the States to impair the power of the Federal government to raise money for Federal purposes by taxing its bonds.

By the adoption of the 14th Amendment (g.v.), to meet the conditions resulting from the abolition of slavery at the close of the Civil War, new restraints were imposed upon the States, the consideration of which has largely occupied the attention of the Supreme Court. It provides that "No State shall make or en-
the domain of the other without danger, and that the safety of our institutions depends in no small degree on a strict observance of this salutary rule. It speaks volumes for the wisdom and caution of the court which is vested with this remarkable power, that in so great a mass of State legislation, some of it crude and undigested, consisting of thousands of volumes, it has not found it necessary to exercise the power much more frequently. It has been thought by foreign observers that a written Constitution, which was framed in the 18th century for 13 feeble States, with 3,000,000 of people of substantially uniform wealth or poverty, scattered along the Atlantic seaboard, and for whose government it was regarded as a precarious experiment, should be found to answer as well in the 20th century for the needs of a great nation of 80,000,000 in 48 States, occupying the breadth of the continent, with gigantic accumulations of individual and corporate property, with conflicting interests and sentiments, and wide differences of social condition. There was much debate in the discussions which resulted in the adoption of the Constitution, whether this instrument could be called into being could reach and control even a people that was expected to occupy the territory which the Treaty of Peace of 1783 secured to the United States, which extended only from the Atlantic to the Mississippi River, and from the lakes to the northern boundary of Florida. Since that time our territory has expanded more than four times, and now embraces insular possessions of vast extent, at enormous distance from the seat of government and half way round the globe.

The fundamental difficulties of time and space have been overcome by the triumphs of steam and electricity, wholly unforeseen and unexpected in 1787, but which now, in the case of the United States and Great Britain alike, have rendered possible the administration of government from London or from Washington on any portion of the earth’s surface. At the time of the adoption of our Constitution it took about 10 weeks to travel the length or breadth of the then United States as it does now to go from New York to Manila, or from London to Peking, and orders of either government which then would have taken months to transmit, now reach their destination so as to be put in execution at the other end of the world in a few hours, and sometimes in a few minutes. But in our case, we can account for the fact that a written Constitution, instead of being torn asunder and left by the way as the nation expanded, as new and wholly unexpected conditions arose, has grown with the growth of the nation, like the hide of an animal from its birth to its maturity, so that it still embraces and covers the whole of our vast national life. We owe it, first, to the wisdom of its framers, who inserted in it only fundamental rules and principles, generally and briefly expressed, leaving it always to Congress to fill in and provide for all the details; and secondly, to the vigorous and masterly manner in which the Supreme Court has exercised its essential and lawful function of construction. By this it has applied the whole instrument and each of its parts to new conditions as they arose, and has developed and strongly asserted the inherent powers of sovereignty intended to be vested in the government of the United States, and necessarily resulting from their existence as a nation. It was our happy fortune that for 34 years, in that critical period of our history when we were to determine whether we were to be a great and powerful nation, adequate for all the needs of a first-class power in the world, or only a league of States like the old Confederation, we had the benefit of the broad and robust intellect of Chief Justice Marshall, to enforce the liberal principles of the Constitution, which the genius of Hamilton had laid down.

In a single paragraph he states the whole theory upon which the court has administered the Constitution, and fitted it to the growing wants and changing conditions of the nation:

*The Government is acknowledged by all to be one of enumerated powers. The principle that it can exercise only the powers granted to it is now universally admitted. But the question respecting the extent of the powers actually granted is perpetually going on, and will probably continue to arise, as long as our system shall exist. The powers of the government are limited, and its powers as conceived. But the sound construction of the Constitution must allow to the National Legislature that discretion with respect to the means by which the powers which are expressly vested in it are to be carried into execution, which will enable that body to perform the high duties assigned to it in a proper and efficient manner. Let the end be legitimate, let it be within the scope of the Constitution, and all means which are appropriate, which are plainly admissible to that end, and which are not prohibited, but are consistent with the letter and spirit of the Constitution, are constitutional.*

Hamilton, in the *Federalist*, declared that the judiciary is beyond comparison the weakest of the three departments of power: that it can never attack with success either of the other two; and that all possible care is requisite to enable it to defend itself against their attacks. Montesquieu, whose works, with Blackstone’s, were the textbooks of constitutional liberty which the framers had constantly in hand, declared that the judicial power is next to nothing. And it was said by another French publicist, *It has no guards, palaces or treasures, no arms but truth and wisdom, and no splendid but the justice and publicity of its judgments.* But the Supreme Court, sustained generally by the confidence and affection of the people, has more than held its own. Keeping carefully within its own limits, it has for the most part labored to keep the other departments of government within theirs, and the powers of the States and of the nation from coming into conflict. In its hands the judicial power has been the force of gravitation which has kept each member of our Federal system in its proper orbit, and maintained the essential harmony of the whole.

The closing scene in the Federal Convention, which made the court in a way the guardian of the Constitution, will be ever memorable. After months of discussion, sometimes violent, more than once approaching the very brink of dissolution, in hopeless despair of coming to any agreement, at last the grand triumph of compromise and mutual concession was accomplished, and the members met to affix their names to the instrument. Hamilton, one of the youngest, acted as scribe, and after Washington had signed first as “President and Deput from Virginia,” inscribed on the great sheet of parchment the name of each State, as the delegates came forward in geographical order to add their names. When all had signed, Frank-
SURLAYA. — SURETYSHIP

lin, the oldest and most famous of them all, pointing to the sun emblazoned behind the chair in which Washington had presided through the whole struggle, said to those about him, "In the vicissitudes of Hope and Fear, I was not able to tell whether it was rising or setting."

After more than a century's trial of their work, the sun which Franklin saw is not yet near the zenith — much has been done, but vastly more remains to be accomplished, and it is still morning in the province of Surahaba.

JOSEPH H. CROATE.

SURABAYA, soo-râ-bâ (Dutch, Soerba-

vaja), Java, (1) the seaport and capital of the province of the same name on the north-east coast of the island of Java. The city is situated on the Strait of Surabaya, which separates Madura Island from Java. It is, next to Batavia, the most important port and commercial station in the Dutch East Indies, and has machine-stores, an arsenal, a mint, sugar and furniture factories, shipbuilding yards and foundries. It exports sugar, coffee and the various products of the region. Pop. about 150,000 including about 10,000 Europeans. (2) The province of Surabaya has an area of 2,327 square miles and a population of over 2,115,000.

SURAJAH Dowlah, soo-râ-jâ dowlâ, the last independent nabob of Bengal, under whom was perpetrated the massacre of the Black Hole (q.v.). He succeeded his grandfather, Ali Verdy Khan, in 1756, and within two months of his accession found a pretext for marching on Calcutta. On the arrival of Clive and Admiral Waterton he retreated to Moorsheadabad, but was routed at the battle of Plassey (1757). He then fled to the Ganges, but was betrayed by a fakir, and was put to death by order of the son of Meer Jaffer, the new nabob. Surajah Dowlah's reign lasted 15 months, his age at the time of his death being barely 20.

SURJAKARTA, soo-râ-kâr'tâ, a town in central Java, connected by rail with Samarang on the north and Surabaya on the east. It is the residence of the native sultan of Surakarta, who is a vassal of the Dutch government and is advised by a resident. The town (pop. 125,000) is the capital of his kingdom, a mountainous but in part very fertile region, with an area of 2,191 square miles and a population of about 1,100,000.

SURAT, soo-rât', India, a city in the Guj-

arat division of Bombay, extends for some distance in crescent form along the south bank of river Tapti, (an iron bridge) in a fertile valley. It is 160 miles by rail north of Bombay. The Nawab's palace lies within the confines of the fort. The remarkable buildings are four handsome Mohammedan mosques, two Parsi fire-temples, several Hindu temples, and a clock-tower (80 feet high). There is also an extensive bazaar, and a Hindu hospital for sick animals. The city in 1512 was burned by the Portuguese, again in 1530 and 1531. The English established themselves there in 1612, and the city came under British rule in 1800. Industry is limited to the manufacturing of cotton and silk goods, shawls, etc., articles of ornamentation, jewelry and ivory objects, indigo and pottery. The exports are cotton and grain. The commercial importance of Surat was established in the 16th century, and it was the starting point for pilgrimages to Mecca. Its decline dates from the removal of the East Indian Company to Bombay. Fire and flood contributed subsequently to its decadence. It flourished during the American Civil War through its cotton export. Pop. about 155,000.

SUREOUF, sûr-kouf, Robert, French naval officer: b. 1773; d. 1827. Much of his life at sea was devoted to privateering and he was known as 'the king of the Corsairs.' From 1798 to 1801 and from 1809 to 1811, he scourred the sea for English merchantmen as Paul Jones did some years previously. He divided between building French ships on shore and scouring the high seas for English merchant vessels. It was his advice to Napoleon: 'Attack rich England in her riches — in her merchant vessels; leave personal chivalry to the line at home and send out light privateers.'

SURETY. See SURETYSHIP.

SURETYSHIP, a word derived from the French sûreté, from the Latin securitas, which means freedom from care. It signifies the obligation of a person to answer for the debt, default or non-performance of another, and to make good any loss occasioned thereby to the extent provided in the contract. The difference between suretyship and guarantee is an essential one, a contract of suretyship being a direct liability to the creditor for the act to be performed by the debtor, whereas a guarantee is liability only for the debtor's ability to perform this act. A contract of suretyship is an immediate and direct undertaking that the act shall be done, and if the act is not done, the surety becomes responsible at once.

The Constitution of the United States makes it impossible for a State to enforce a law which might be construed as impairing the rights of a creditor under a contract of suretyship, but like other contracts it may be vitiated and annulled through fraud or duress in the execution. The surety is entitled to such information both from creditor and debtor as will enable him to know the nature of the obligation which he is assuming, and if there is fraudulent misrepresentation or suppression of the fact with the purpose of obtaining his agreement to the undertaking the surety can obtain relief in a court of equity. On the other hand his relief would not be granted against innocent parties who had, without notice from the surety, incurred expenditure or assumed obligations on account of the existence of the suretyship contract. Of course in such a case the surety would have a right to redress from the creditor or debtor, or both, who had caused him loss by deceiving him.

It should be understood that there is no obligation on the part of the creditor or of the
SURF-BIRD — SURFACE TENSION
debtor to disclose all facts relating to the risk,
but only those the withholding of which, if
known to them, or either of them, would con-
stitute intent to mislead. The surety, on the
other hand, is expected to use reasonable judg-
ment and precaution in making the contract.
The presumption of law is that the suretyship,
the surety’s signature being admitted, is valid,
and upon him rests the onus of attacking its
validity, if he so desires.

The surety’s responsibility cannot be changed
or made contingent, in any manner without his
consent, and should any change be
made in the contract without such consent, the
surety is discharged from his obligation. It
does not matter whether the change would be
advantageous to the surety or otherwise; he has
a right to stand upon the original terms,
and cannot be held responsible for any different
terms. This applies also to any extension of
the term of credit specified in the contract
without the surety’s approval in legal form.

Upon the discharge of his obligation by the
debtor, the surety is of course released. The
surety is likewise released by tender of pay-
ment by the debtor and refusal to receive it by
the creditor. In some States the surety is
released if the creditor does not sue the prin-
cipal of the surety. Should the
debtor default and the surety have to pay,
the surety becomes entitled to all the rights and
securities previously held by the creditor
against the debtor. If there are several sure-
ties, and the creditor’s claim is enforced against
one only, the latter can compel his co-sureties
to pay their several shares, and he also has a
claim against the principal for the amount
which he has expended in meeting the obligation.
See GUARANTEE.

SURF-BIRD, a shore-bird (Aphissa vir-
gates), in some districts of its own be-
tween the sandpipers and plovers. It is about
10 inches long, with the wing seven, dark
brown above, lighter on the wing coverts, with
white spots and stripes on the head and neck;
upper tail-coverts and a central pair of tail
feathers are white, the latter terminated with brownish black; un-
der parts white, tinged with ash in front, each feather having a brownish black crescent. The bill is about as long as the head, with a short, ovate, rather compressed sides; wings long and pointed. It is found on the Pacific Coast of North and South America, and in the Sand-
wich Islands, migrating from northern to tem-
perate regions in winter and back again in summer. It is generally seen on the edge of
steep rocks, among the retreating waves, search-
ing for small mollusks and marine animals, allowing the surf sometimes to dash over it,
whence the common name; its flight is short,
with a quick and jerking motion.

SURF-CLAM. See CLAM.

SURF DUCK, or SURF SCOTER. See Scot-
er.

SURF-FISH, one of the many small ovoid
fish of the family Embididae, related to the
percoids, which abound upon the Pacific
Coast of North America, where they are found
numerously in the surf on sandy beaches, and
in the mouths of rivers. They are often gayly
colored, sometimes in extraordinary patterns
of spots or bars; and are easily caught but not
valued much as food. The most familiar one
is Amphistium argenteus; several others are
commonly known as the blue, black, red and
white perchles, the alionoe, etc. All are vivipa-
rous.

SURF-SMELT, a small, eminently tooth-
some smelt (Hyphomemas pritcheri), numer-
ous along the coast of California and north-
ward, where it spawns in the surf, and is
caught in great quantities in nets. See Sme-
Rishes.

SURFACE, Joseph, a character in Sheri-
dan’s comedy, ‘The School for Scandal.’ He
is a mean hypocrite who affects great serious-
ness and sentimentality.

SURFACE. (1) A physical surface may be
defined as formed by the boundaries or limiting
portions of a given body. (2) A mathematical
surface is the boundary between two given por-
tions of space. It may be of various orders, a
plane surface being of the first order, a quadric
surface of the second order, etc. A surface
through all points of which a straight line may
be so drawn as to rest entirely within the said
surface, is termed a ruled surface. The cone,
cylinder and sphere are examples of this class.
A surface is said to be of the nth order when it
is intersected at n points, either imaginary or
real, by a given arbitrary line. For a treatment
of the subject, consult Eisenhart, L. P., ‘Treat-
ise on Differential Geometry, on Curves and
Surfaces’ (Boston 1909); Michaelis, M. L.,
‘Dynamics of Surfaces’ (New York 1914); Smith,
Charles, ‘Solid Geometry’ (3d ed., New
York 1891).

SURFACE TENSION, that property of
liquids in virtue of which they tend to take
such a form as to have the smallest surface
possible. The name ‘surface tension’ has refer-
ence to the fact that liquids, when freed
from the action of gravity and other compara-
tively powerful forces, behave as though their
surfaces were elastic membranes, which are
everywhere in a state of uniform tension. Be-
ginners in the study of physics often get the
idea, from their textbooks, that this hypotheti-
cal tension is real and that the surface of a
liquid really is membranous in nature, and sub-
ject to an actual, physical tension. This is not
at all the case; for the behavior of the liquid
is due to an entirely different cause, as will be
understood by reference to Fig. 1. AB here
represents a liquid surface, and m m m m m
represents a molecule of the liquid, which is
originally in the interior of the liquid, but
which is removed from it in the manner illus-
trated by the successive figures 1, 2, 3, 4 and 5.
Consider, first, the state of the molecule m in
the position 1. It is here surrounded by the
liquid on all sides, and the attractive influence
that the other molecules of the liquid exert
upon it is sensibly the same in all directions.
The circle that is drawn about m represents a
sphere whose radius is the *radius of sensible
molecular attraction*; that is, it is equal to the
(unknown) distance at which we may suppose
that the attraction of one molecule of the liquid
for another one ceases to be sensible. The at-
tractive influence of those parts of the liquid
which are external to this sphere being by
hypothesis insensible, we may regard m as in-
fluenced solely by such molecules as are within
a sphere of the radius shown. It is easily seen, therefore, that the attraction of the liquid for $m$ will be the same in all directions (and therefore without any resultant effect), so long as the sphere remains totally submerged. But when the molecule $m$ approaches the surface so nearly that a part of its sphere projects into the air as shown at 2, it is equally evident that the attractive force upon $m$ is no longer the same in all directions. In order to make it so, we should have to cut off, from the bottom of the sphere at 2, a segment equal to the segment that projects into the air, as indicated by the little shaded area. The mass of fluid that lies between this shaded segment and the surface of the liquid is without any resultant effect upon the phenomena that are manifested by liquid films, and by masses of liquid that are freed from the influence of gravity by being suspended in other liquids with which they will not mix, but which have the same density as the liquid to be studied. Olive oil can readily be freed from the action of gravity by submerging it in a mixture of alcohol and water, whose composition is regulated by trial until the mixture has precisely the same specific gravity as the oil. A mass of oil which is submerged in this manner, and is not constrained in any way, at once assumes a spherical form; for the sphere has a smaller surface than any other solid of the same volume.

The existence of surface tension can be shown readily and strikingly, even in a large mass of water, by several very simple experiments. Of these, the camphor-movement experiment is one of the best known. To perform it, a perfectly clean vessel is filled with clean water, some of the water being allowed to flow over the sides of the vessel, so that any superficial impurities may be washed away. Very fine and due to the fact that the surface tension of a solution of camphor in water is less than that of pure water. The camphor particles do not dissolve evenly on all sides; and the horizontal pull exerted upon them by the water is greatest in those directions in which the concentration of the solution in immediate contact with the particles is least. Hence the motions. The great importance of absolute cleanliness in this experiment is well illustrated by touching with a slightly greasy finger a water surface upon which camphor particles are in rapid motion. The entire surface becomes contaminated almost instantly, so that the camphor movements become deadened, or cease altogether.

The effects of surface tension are observable in large masses of liquid, where those masses come in contact with the walls of their containing vessels. The slight elevation of the water in a drinking glass, where the water touches the glass, is due to this cause. This particular phenomenon is more marked in the case of a glass tube of small diameter, dipping in a vertical position into a vessel of water (or any other liquid which actually wets the glass). Let the glass tube be inserted into the water, so that it is wetted up to a certain level, and let the tube be then raised slightly. The glass, in the region which has been submerged below the general level of the water and is now raised above it again, adheres to the water, and as the tube is raised, the column of water within it sinks at the centre, so that its surface becomes concave, as is illustrated in the diagram. The weight of that part of the water within the tube which stands above the general level of the water in the external vessel (that is, the weight of that portion which lies between the actual water surface in the tube and the dotted horizontal line), is sustained by the tension of the curved surface (or "meniscus") that bounds the column at the top; this tension acting everywhere in the direction of the surface of the water, and therefore having an obliquely-upward di-
resection around the edges, and hence a vertical component, which is capable of sustaining the water in the tube. In the case of a liquid which does not wet the tube (for example, in the case of mercury and glass), the curvature of the liquid surface is in the opposite direction from that observed with water and glass; that is, the meniscus is convex upwards, as shown in Fig. 3, and the liquid in the tube stands at a lower level than corresponds to the general level of the liquid surface in the containing vessel. In a barometer, the meniscus of the column is convex upward, and the depression of the column due to the surface tension of the mercury is usually quite sensible; so that in order to be in a position to know the exact height at which the mercury in the column would stand if the tube were large enough in diameter for the effects of surface tension to be negligible, it is necessary to investigate, very carefully, the way in which the depression varies with the diameter of the tube, and with the height of the meniscus itself. Numerous observers have made extensive investigations of this sort, and have given their results in tables. A very good table of this kind, due to Mendeleeff, is given in Guillaume’s ‘Thermométrie de Precision,’ and other tables will be found in nearly all of the works upon meteorology. The property of liquids in virtue of which they stand, in a vertical tube, at an elevation different from that in the vessel into which the tube is dipped, is commonly called ‘capillarity,’ reference to the small diameter of the tube in which the effect is most noticeable (Latin, capillus, ‘hair’).

The surface tension of a liquid is measured by the horizontal pull that the liquid can exert upon a straight line one unit in length, lying in its surface; the pull being perpendicular, of course, to the direction of the line. The accompanying table contains the surface tensions of various liquids as determined by Quincke, and quoted by Maxwell. Mercury, for example, is capable of exerting a pull of 21.58 grains upon a straight line one inch long, lying in its surface. The value of the surface tension of water given in this table is certainly too great. Brunner found it to be 75.1 dynes per centimeter, and Wolf found 76.3 and 77.3. Rayleigh’s determination, based upon a study of the wave-length of ripples, gave 73.9 dynes at 18° C.; and T. Proctor Hall found that at 7° C. the surface tension of water, in the same units, is given by the expression.

$$75.14 - 0.1407.$$

Allan D. Risteen.

SURFACES, Theory of. Surface, in the mathematical sense, is the common boundary of two contiguous regions of space. The developments in this vast field of mathematical investigation are essentially of modern origin. The geometers of the Greek school were acquainted with some of the elementary properties of a few surfaces, notably those of sphere, cylinder and cone, but the systematic and fruitful study of surfaces began with their representation by means of equations in Cartesian co-ordinates (see GEOMETRY, Cartesian). This was not done until the method of co-ordinates had been employed with success in the study of plane curves, whereupon its application to surfaces presented itself as a natural extension. According to Cantor, ‘Geschichte der Mathematik,’ Parent (1666-1716) was the first to represent surfaces analytically by means of a single equation $F(x, y, z) = 0$. To each set of values of $x, y, z$ satisfying this equation corresponds a point of the surface. With the introduction of co-ordinates two distinct phases in the study of surfaces present themselves. On the one hand the surface is defined in some purely geometric way, and the problem is to find an equation analytically representative of the surface. On the other hand an equation is assumed, and the problem is to arrive at the properties of the surface from its analytical definition. In the first case no less than in the second, the deduction of geometric properties proceeds, in the main, along analytical lines. It is at once evident that the second phase of the general problem greatly broadens the scope of investigation, and it is from this point of view that the mathematicians have studied the surfaces defined by algebraic equations of second, third, fourth, and higher degrees. The algebra brings in imaginary roots, and this leads to the introduction of surfaces that are altogether imaginary, and to the consideration of imaginary points and elements in connection with real surfaces.

In what has been said thus far the point has figured as the primitive element of the surface, and in connection with it the surface is a two-dimensional continuum of points. With the expansion of the subject additional primitive elements were introduced, and the plane and the line, and from the standpoint of the new elements the surface may be regarded as a
two-dimensional continuum of planes, i.e., as the envelope of its tangent planes, or as a three-dimensional continuum of lines, i.e., the envelope of its tangent lines. The theory of a surface as the envelope of its $w^2$ of tangent lines constitutes a special chapter in the general theory of complex of straight lines (see \textit{Geometry, Line, and Allied Theories}). Along with the analytical method, the synthetic or projective method has been employed, and with special elegance and completeness in the case of surfaces of the second order. With this brief introduction we now pass to a more detailed account of the developments in this branch of mathematics.

1. Algebraic Surfaces in General.—Any surface which can be analytically expressed by an algebraic equation between the Cartesian co-ordinates $x, y, z$ of a point of space is called an \textit{algebraic} surface. The \textit{order} of the surface is the number of points of intersection (real or imaginary) of the surface by an arbitrary straight line. The order of the surface is obviously the same as the degree of its equation. The \textit{class} is the number of tangent planes of the surface that pass through an arbitrary line. When there is no singularity (see 7) on the surface the class is $n(n-1)$. The \textit{rank} of the surface is the order of a circumscribing cone whose vertex is an arbitrary point of space. The rank is $n(n-1)$. The intersection of the surface by a plane is a curve of nth order, and, by the foregoing, the class of this curve is the same as the rank of the surface.

2. The Plane.—This is the simplest of all surfaces, and its equation in the variables $x, y, z$ is of the first degree: $Ax + By + Cz + D = 0$, in which $A, B, C, D$ are constants. It is the only surface of first order.

3. Surfaces of the Second Order, or Quadric Surfaces.—The earliest investigations were connected with the surfaces of the second order, namely, those defined by the general equation of the second degree: $Ax^2 + By^2 + Cz^2 + 2Fxy + 2Gyz + 2Hxz + 2Lx + 2My + 2Nz + P = 0$.

This equation contains 10 coefficients which enter homogeneously. However, only the nine ratios of the coefficients are essential, as the equation may be divided through by any coefficient that is not zero. From this fact comes an important theorem. The substitution of the co-ordinates of a given point in the general equation imposes one equation of condition upon the coefficients; nine such equations determine the ratios of the coefficients, and hence the equation, and with it the surface. The theorem follows: A surface of second order is in general determined by nine points through which it is to pass.

4. Classification of Quadric Surfaces.—There are in all 16 surfaces of the second order, when the purely imaginary and degenerate cases are included in the notation. The classes of the individual surfaces varies with the principle employed. The principle of division may be based on analytical criteria or on geometrical characteristics. Four different varieties of geometrical classification are known. In one the surfaces are divided into (a) the surfaces with centre or central surfaces, (b) the non-central surfaces. A second classification gives, (a) ruled surfaces with real generating lines (see 16), (b) non-ruled surfaces (analytically these latter surfaces are ruled surfaces with imaginary generating lines). A third classification rests upon the presence or absence of vertices on the surface. For example, a cone has a vertex and two intersecting planes are a degenerate form of a surface of second order with the line of intersection as a line of vertices. An ellipsoid is without a vertex. The fourth classification is based upon the nature of the cone that is cut from the surface by the plane at infinity.

We now present a classification based upon analytical criteria. This is effected by means of the values of two polynomials $d$ and $D$, functions of the coefficients, and of the roots $k = \lambda, \mu, \nu$, of a cubic equation in $k$ called the discriminating cubic. They may be conveniently put in the determinant form, as also the cubic equation:

$$
\begin{vmatrix}
A & H & G & L & D \\
H & B & F & M & H \\
G & F & C & N & G \\
L & M & N & P & L \\
D & H & G & L & A - k - H - G - L = 0
\end{vmatrix}
$$

I. Surfaces for which $D > 0$.

(a) $D > 0$, (i) Ellipsoid, real, if $\frac{D_1}{d}, \frac{D_2}{d}, \frac{D_3}{d}$ are all negative.

(ii) Hyperboloid of one sheet if two of the quantities are negative.

(iii) Hyperboloid of two sheets if one of the quantities is negative.

(iv) Ellipsoid, imaginary, if all the quantities are positive.

These are \textit{surfaces with centre}. By a suitable translation of the co-ordinate axes, by the centre the general equation can be thrown into the form $\lambda x^2 + \mu y^2 + \nu z^2 + d = 0$, in which $d = \frac{D}{D}$ and $\lambda, \mu, \nu$ are the roots of the discriminating cubic.

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{ellipsoid.png}
\caption{Ellipsoid.}
\end{figure}

(b) $D = 0$, (i) Elliptic paraboloid if $\lambda$ and $\mu$ have the same sign.

(ii) Hyperbolic paraboloid if $\lambda$ and $\mu$ have different signs.

When $D = 0$, one of the roots $\lambda, \mu, \nu$ is zero, and it is here assumed that $\nu = 0$. By a suitable transformation of the origin of co-ordinates to a point of the surface, the equation may be made to take the form $\lambda x^2 + \mu y^2 + 2\rho x = 0$.

The surfaces (a) and (b) are \textit{surfaces without vertices}. 

\textbf{Vol. 26 — 5}
II. Surfaces for which $d = 0$.

$(y) \quad D < 0$,

(i) Cone, real, if $\lambda$, $\mu$, $\nu$ are not all of same sign.

(ii) Cone, imaginary, if $\lambda$, $\mu$, $\nu$ are of same sign.

By taking the origin at the vertex of the cone the equation may be brought into the form $\lambda x^2 + \mu y^2 + \nu z^2 = 0$.

$(y) \quad D = 0$,

(i) Elliptic cylinder, if $\lambda$ and $\mu$ are of same sign and $d \geq 0$.

(ii) Hyperbolic cylinder, if $\lambda$ and $\mu$ are of different signs and $d \geq 0$.

(iii) A pair of intersecting planes, real or imaginary, if $d = 0$.

(iv) Parabolic cylinder; or two parallel planes, real or imaginary (if all the subdeterminants of $D$ are zero).

The ruled surfaces among quadric surfaces fall into two categories: (1) the cone and cylinder, each containing one set of generating lines infinite in number; (2) the hyperboloid of one sheet and the hyperbolic paraboloid, each containing two sets of generating lines infinite in number. On the two last-named surfaces no two lines of one set intersect, but each line of one set intersects all the lines of the other set.

5. Surfaces of the Third Order, or Cubic Surfaces.—A considerable number of theorems about these surfaces are now known, though their properties have by no means been so exhaustively studied as in the case of quadric surfaces. There are two especially distinguishing properties to be noted concerning them: first, on the general surface there are 27 right lines; second, there is related to the surface a pentaedron whose edges and vertices lie on the Hessian of the surface. When there is no singular point on the cubic surface its equation can be thrown into the form $c_1 W_1 + c_2 W_2 + c_3 W_3 + c_4 W_4 + c_5 W_5 = 0$, where $W_1, W_2, \ldots$ are linear in $x, y, z$ and the equation $W_1 + W_2 + W_3 + W_4 + W_5 = 0$ holds identically. The Hessian of the cubic is

$$
\frac{1}{c_1 W_1} + \frac{1}{c_2 W_2} + \frac{1}{c_3 W_3} + \frac{1}{c_4 W_4} + \frac{1}{c_5 W_5} = 0,
$$

a surface of fourth order. It contains the 10 edges and the 10 vertices of the pentaedron formed by the five planes $W_1 = 0, W_2 = 0, \ldots$. The vertices are double points (see VII) of the Hessian. For particulars as to these surfaces consult Salmon, 'Geometry of Three Dimensions,' and also Stürmer, 'Synthetische Untersuchungen über Flächen dritter Ordnung' (Leipzig 1857).

6. Surfaces of Fourth Order.—Of these only special surfaces have been thoroughly discussed, among them the ruled surfaces and the Kummer surface. The Kummer surface contains 16 double points and 16 singular planes. Each of the planes is tangent to the surface along a conic and contains six of the double points, and through each double point pass six of the singular planes. Consult Salmon-Friedler, Vol. II, and Kummer, 'Berliner Abhandlungen' (1866). The results obtained in the study of algebraic surfaces of order higher than the fourth are of more or less fragmentary character and need not be referred to in this brief sketch.

7. Ordinary and Singular Points.—In general the $n$ points of intersection of a line and surface are distinct, but if a point $P$ appears as $k$ coincident points among the $n$ intersections for every straight line through it, it is called a $k$ multiple point of the surface. When $k = 2$ it is a double point, when $k = 3$ a triple point. Multiple points are singular points. Through a double point on a surface an in-
finity of lines can be drawn each of which will pass through a third point on the surface infinitely near the double point. The locus of these lines is a cone of second order. There are three cases: (1) the cone is a proper cone and the double point is called a conical point; (2) the cone degenerates into two intersecting planes and the point is a biplanar point; (3) the cone degenerates into two coincident planes and the point is a uniplanar point or pinch point. There may be a curve of double points on a surface: for example, the curve of intersection of a surface by itself is such a locus, as is also the curve of contact of two sheets of the same surface with each other. For a detailed study of the character of a surface in the neighborhood of a double point consult Rohn, 'Mathematische Annalen, 22' (1883). As the study of a surface proceeds in general from the equation of the surface, it is to the analysis we must look for a definitive criterion distinguishing ordinary and singular points. A point \( s, t, x, y, z \) of a surface \( F(x, y, z) = 0 \) is said to be ordinary, if the \( F \) function is developable in an entire series in the neighborhood of \( x, y, z, \) and if the three first derivatives \( \partial F/\partial x, \partial F/\partial y, \partial F/\partial z \) do not simultaneously vanish at the point. All other points are singular points.

8. General Considerations. Curvilinear Co-ordinates.—Modern progress in the theory of surfaces begins with the appearance in 1827 of Gauss' paper, 'Disquisitiones generales circa superficies curvas' (translated into German in Ostwald's 'Klassiker der exakten Wissenschaften'; into English by Morehead and Hiltebeitel, Princeton). Two things in this classical production have profoundly affected subsequent developments in the theory. The first was the systematic employment of curvilinear co-ordinates, and therewith a demonstration of the great advantages which could be derived from their use; the second was the conception of a sury extension, not rigid but flexible, which could be made to assume new shapes by bending without stretching. All surfaces derived from a given surface by bending are said to be applicable, or developable, upon each other. It is clear that the geometry of figures on such surfaces is the same. The analytical criteria, whether two given surfaces are applicable upon each other, constitute one of the interesting chapters in the general theory. In expressing the Cartesian co-ordinates \( x, y, z \) as functions of two variables \( u, v \) called parameters:

(A) \( x = \phi(u, v), \ y = \psi(u, v), \ z = \gamma(u, v) \)

a new form of representation of surfaces is established. The elimination of \( u \) and \( v \) would obviously lead to one equation, \( F(x, y, z) = 0 \). If \( u \) be given a definite value \( u_0 \) and \( v \) be allowed to vary, a curve will be generated lying on the surface (see Curves of Double Curvature). The curve is called the \( u \) curve, that is, it is named by the special value of the parameter at all its points. Assigning a second value to \( u \), say \( u_1 \), and allowing \( v \) again to vary, there would be formed the \( u_1 \) curve of the surface. In this way there could be formed an \( \infty \) of curves on the surface constituting the family of \( u \) curves. Similarly, there is a family of \( v \) curves each characterized by a definite value of \( v \) while \( u \) is variable. Each point of the surface is the intersection of a \( u \) curve and a \( v \) curve, and the curves are called its curvilinear co-ordinates. One may thus speak of the point \( (u_0, v_0) \) of the surface, or in general of the point \( (x, y, z, u, v) \), in place of referring to it by its Cartesian co-ordinates. Both co-ordinate systems are put in evidence by writing the point in the form \( (x, y, z; u, v) \). A restriction upon the values \( u \) and \( v \) may take, such as an equation \( f(u, v) = 0 \), defines a curve on the surface.

9. Tangent Plane. Principal Normal Sections.—If to all the curves on a surface passing through an ordinary point \( P(\xi, \eta, \zeta; u, v) \), tangents be drawn at \( P \), the line will lie in a plane called the tangent plane at \( P \). Its equation is:

\[
\left( \frac{\partial x}{\partial u} dx + \frac{\partial x}{\partial v} dv \right) (\xi - x) + \left( \frac{\partial y}{\partial u} dx + \frac{\partial y}{\partial v} dv \right) (\eta - y) + \left( \frac{\partial z}{\partial u} dx + \frac{\partial z}{\partial v} dv \right) (\zeta - z) = 0.
\]

where \( \xi, \eta, \zeta \) are the current co-ordinates of the points of the plane.

The line perpendicular to the tangent plane at \( P \) is the normal of the surface at \( P \). Every plane through the normal is a normal plane, and the sections made by them with the surface are normal sections.

10. The Fundamental Quadratic Forms and the Fundamental Magnitudes of the First and Second Order. The Fundamental Equations.—The entire theory of a surface is implicitly involved in two fundamental quadratic differential forms, and in three fundamental differential equations. The first form is the expression for the square of the arc length \( ds \) on the surface between two infinitely near points \( P(x, y, z; u, v) \) and \( P_1(x + dx, y + dy, z + dz; u + du, v + dv) \). This is found to be:

\[
(\delta) \quad ds^2 = dx^2 + dy^2 + dz^2 = Edu^2 + Fdu dv + Gdv^2,
\]

where:

\[
E = \left( \frac{\partial x}{\partial u} \right)^2 + \left( \frac{\partial y}{\partial u} \right)^2 + \left( \frac{\partial z}{\partial u} \right)^2,
\]

\[
F = \left( \frac{\partial x}{\partial v} \right)^2 + \left( \frac{\partial y}{\partial v} \right)^2 + \left( \frac{\partial z}{\partial v} \right)^2,
\]

\[
G = \left( \frac{\partial x}{\partial u} \right)^2 + \left( \frac{\partial y}{\partial u} \right)^2 + \left( \frac{\partial z}{\partial u} \right)^2.
\]

The second quadratic differential form is the expression for twice the distance, \( d \), from the point \( P \) to the tangent plane at \( P \):

\[
(\delta) \quad 2d = |D| = \sqrt{EG - F^2},
\]

where:

\[
D = \begin{vmatrix}
\frac{\partial x}{\partial u} & \frac{\partial y}{\partial u} & \frac{\partial z}{\partial u} \\
\frac{\partial x}{\partial v} & \frac{\partial y}{\partial v} & \frac{\partial z}{\partial v} \\
\frac{\partial x}{\partial w} & \frac{\partial y}{\partial w} & \frac{\partial z}{\partial w}
\end{vmatrix}
\]

The six magnitudes \( E, F, G; D, D', D'' \) on account of their importance are called funda-
mental magnitudes: the first three as containing derivatives of the first order are called the fundamental magnitudes of the first order; the second three as containing derivatives of the second order are called the fundamental magnitudes of the second order. The six magnitudes are not independent of each other, but are connected by three partial differential equations called the fundamental equations of the surface. These may be obtained by differentiation from the foregoing equations. They are:

\[
\begin{align*}
DD'' &= \frac{D^3}{EG} \\
&= \frac{1}{2(EG - F^2)} \left[ \frac{\partial^2 E}{\partial u \partial v} + \frac{\partial E}{\partial v} \frac{\partial G}{\partial u} - 2 \frac{\partial G}{\partial u} \frac{\partial F}{\partial v} \right] \\
&\quad + \frac{4(EG - F^2)}{E} \left[ \frac{\partial^2 E}{\partial u^2} + \frac{\partial E}{\partial u} \frac{\partial G}{\partial u} - 2 \frac{\partial G}{\partial u} \frac{\partial F}{\partial u} \right] \\
&\quad + \frac{4(EG - F^2)}{G} \left[ \frac{\partial^2 E}{\partial v^2} + \frac{\partial E}{\partial v} \frac{\partial G}{\partial v} - 2 \frac{\partial G}{\partial v} \frac{\partial F}{\partial v} \right] \\
&\quad + \frac{4(EG - F^2)}{F} \left[ \frac{\partial^2 E}{\partial u \partial v} + \frac{\partial E}{\partial u} \frac{\partial G}{\partial v} - 2 \frac{\partial G}{\partial u} \frac{\partial F}{\partial v} \right] \\
&\quad - 2 \frac{\partial^2 E}{\partial u \partial v} + \frac{\partial^2 E}{\partial u^2} + \frac{\partial^2 E}{\partial v^2}.
\end{align*}
\]

\[
\begin{align*}
D'' &= \frac{D'}{du} \\
&= \frac{1}{2(EG - F^2)} \left[ D'' \left( \frac{\partial E}{\partial u} - \frac{\partial G}{\partial u} \right) + \frac{\partial^2 E}{\partial u^2} - 2 \frac{\partial G}{\partial u} \frac{\partial F}{\partial u} \right] \\
&\quad - D' \left( \frac{\partial E}{\partial u} - \frac{\partial G}{\partial u} \right) + 2 \frac{\partial E}{\partial u} \frac{\partial F}{\partial u} - 2 \frac{\partial F}{\partial u} \right) \\
&\quad + D'' \left( \frac{\partial E}{\partial F} - \frac{\partial G}{\partial F} \right) + \frac{\partial^2 E}{\partial u^2} - 2 \frac{\partial G}{\partial u} \frac{\partial F}{\partial u} \right) \right].
\end{align*}
\]

Equation (\(y\)) was established by Gaus in the paper previously cited. The first member of this equation, \((\frac{D''}{D'})^2\), has an interesting geometrical significance in connection with the curvature of the surface (see 12). Equations (d) and (e) were determined by Mainardi (1857) and 11 years later, independently, by Codazzi. The three equations are known as the Gauss-Mainardi or Gauss-Codazzi equations. It is evident that \(E, F, G\) satisfy the conditions: \(E > 0, \ G > 0, \ FG - F^2 > 0\). To Bonnet is due the theorem that a surface is completely determined in all respects, except only as to its position in space, by six given functions \(E, F, G, D, D', D''\) of two variables \(u, v\), provided that the six functions satisfy the three fundamental equations (1), (d), (e), and the three inequalities. The determination of the Cartesians variables \(x, y, z\) as functions of \(u, v\), depends upon the integration of a differential equation of the Riccati type (see Equations, Differential).

11. Curvature of Curves Traced upon the Surface Theorems of Mensnier and Euler. Principal Radii of Curvature. The problem of the curvature of curves traced on the surface through \(P\), and the relations of these curvatures, is simplified by considering first only those curves that have a common tangent at \(l\). Let the common tangent be \(PT\), and, for the sake of definiteness, let it be the tangent through \(P(u, v)\) and the infinitely near point \(l(u + du, v + dv)\). Conceive as drawn the sphere whose radius \(R\) and centre \(l\) are the radius of curvature and centre of curvature (relative to \(P\)) of the normal section with the tangent line \(PT\). *Mensnier's theorem states* that the plane of osculation of any curve through \(P\) with tangent line \(PT\) intersects the sphere in the circle of curvature of the curve relative to \(P\). If \(\tau\) is the angle between the plane of osculation of the curve and the normal section, and \(R\) the radius of curvature of the curve, then \(R = R \cos \tau\).

It remains to express the value of \(R\). *Newton's theorem concerning curvature of plane curves gives immediately*:

\[
\frac{1}{R} \frac{ds}{dr} = Edu^3 + 2Ddu dv + D''dv^3.
\]

To each value of \(\frac{dv}{du}\) correspond a tangent direction at \(P\) and a normal section, and the equation above determines the curvature of this section relative to \(P\). There are two values of \(\frac{dv}{du}\) for one of which \(R\) takes a maximum value, and for the other a minimum value. By the usual methods employed in maxima and minima the two values of \(\frac{dv}{du}\) are found to satisfy the equation:

\[
(FD'' - GD') \left(\frac{dv}{du}\right)^2 + (ED'' - GD) \frac{dv}{du} + PD = 0,
\]

and the two corresponding values of \(R\), viz., \(R_1\) and \(R_2\), the equation.

\[
(FD'' - GD')R^2 - (ED'' - 2FD + GD)R + EG - F = 0.
\]

The two tangent directions at \(P\) thus distinguished are at right angles to each other and are called the principal directions of curvature at \(P\), and the corresponding normal sections are the principal normal sections. \(R_1\) and \(R_2\) are called the principal radii of curvature of the surface at \(P\).

*Euler's theorem expresses the radius of curvature \(R\) of any normal section in terms of the principal radii of curvature and an angle \(\phi\). The equation is:

\[
\frac{1}{R} = \frac{1}{R_1} \cos^2 \phi + \frac{1}{R_2} \sin^2 \phi,
\]

where \(\phi\) is the angle between the normal section in question and the principal normal section corresponding to \(R_1\). In Euler's and Menger's theorem the theory of the curvature of curves traced on a surface finds a satisfactory exposition.

12. Curvature of the Surface. *Gauss Spherical Representation.—Various definitions of curvature of a surface have been suggested, of which three have found general acceptance. The three curvatures differ in kind. It is found that the mean value of the curvatures of all the normal sections through \(P\) (relative to \(P\)) is one-half the sum of the curvatures of the principal normal sections at \(P\), viz.,

\[
\frac{1}{2} \left( \frac{1}{R_1} + \frac{1}{R_2} \right).
\]

It would be natural to take this
value as the mean curvature of the surface at $P$, but the mathematical world has chosen to give the name mean curvature to the double of the quantity. Having regard to (9), one has

(4) Mean curvature at a point

$$k = \frac{1}{R_1 R_2} \left( \frac{ED'' - 2FD' + GD}{EG - F^2} \right).$$

The other two curvatures are connected with Gauss's method of representing a surface upon a sphere by means of parallel normals. At a point $P$ of the surface the positive normal is drawn; from the centre of the sphere a radius is drawn parallel to the normal; the extremity $p$ of this radius is called the spherical image or picture of $P$. When $P$ describes a curve on the surface, $p$ describes a curve on the sphere, and, in general, to an area on the surface corresponds an area on the sphere. Gauss has called the area on the sphere the total curvature (curvatura integra) of the corresponding area on the surface. If $\Delta s$ is an infinitely small area on the surface above the point $P$ and $\Delta s_1$ its total curvature, the ratio

$$\frac{\Delta s}{\Delta s_1}$$

is called the measure of curvature (curvatura specifica) or Gauss curvature of the surface at $P$. Gauss showed that this ratio is

$$\frac{1}{R_1 R_2},$$

whence the theorem, that the measure of curvature at a point is equal to the product of the principal curvatures of the surface at the point. Using $K$ to represent this curvature, and having regard to (9),

(5) Measures of curvature at a point

$$K = \frac{1}{R_1 R_2} \left( \frac{DD'' - DD'^2}{EE - F^2} \right).$$

13. Dupin's Indicatrix. Lines of Curvature, Asymptotic Lines. Conjugate Directions.—To ascertain the nature of the surface in the immediate neighborhood of a point $P$, one intersects the surface by a plane parallel to and infinitely near the tangent plane at $P$. The curve of section is called the indicatrix relative to $P$. The indicatrix is, in general, a conic whose equation is (6) when $d$ is constant. As $d$ is infinitely small of second order, the curve may be regarded as lying in the tangent plane at $P$ with $P$ as centre. Taking the tangents of the principal directions of curvature at $P$ as co-ordinate axes ($\xi_1$, $\xi_2$), equation (6) becomes

$$\frac{\xi_1^2}{\xi_1^2} + \frac{\xi_2^2}{\xi_2^2} = 1.$$

When $R_1$ and $R_2$ have like signs the indicatrix is an ellipse, and when the signs are unlike it is a hyperbola. In the first case $P$ is an elliptic point of the surface and the neighborhood of $P$ is convex-convex relative to the tangent plane; in the second case $P$ is a hyperbolic point and the neighborhood of $P$ is convex-concave. If either $R_1$ or $R_2$ is infinite at $P$, the indicatrix is two infinitely near parallel right lines. $P$ is then called a parabolic point. A surface may contain a region of elliptic points and a region of hyperbolic points. The curve separating the two regions is a locus of parabolic points. For a surface of parabolic points, $K$ must be identically zero (see 17).

By reference to the indicatrix at every point of the surface, one may define the system of lines of curvature as the two series of orthogonally intersecting curves ($\omega^1$ in each series) whose tangent directions coincide with the principal axes of the indicatrix, i.e., with the principal directions of curvature (see 11). From the definition it follows that ($\psi$ is the differential equation of the lines of curvature. The integration of ($\psi$) for any surface whose fundamental magnitudes are known furnishes the two series of lines of curvature of the surface. It is characteristic of a line of curvature that the normals of the surface at two consecutive points of the curve intersect, and this property is sometimes given as the definition of the curve. By reference to this property a ready means is occasionally afforded for identifying the lines of curvature; for example, on a surface of revolution one of the series of lines of curvature consists of the meridians and the other series of the parallel circles. The sphere and plane form a class apart from all other surfaces as regards lines of curvature, for any curve on either surface is a line of curvature. To Joachimsthal is due the theorem that, if two surfaces intersect in a constant angle and the curve of intersection is a line of curvature on the one, it is also a line of curvature on the other. It follows in particular that, if a plane or sphere intersects a surface in a constant angle, the curve of section is a line of curvature.

Again, by reference to the indicatrix, one defines the system of asymptotic lines as the two series of intersecting curves whose tangent directions coincide with the asymptotes of the indicatrix. Asymptotic lines are real only in the hyperbolic region of the surface. The differential equation of asymptotic curves is

$$2D'ds + 2D'ds_1 + 2D''ds_2 = 0.$$

It is characteristic of an asymptotic line that the plane of osculation at any point of it is the tangent plane of the surface at the point.

Two conjugate diameters of the indicatrix of a point give conjugate directions at the point; and reference to any direction there is a conjugate. A system of curves consisting of two series of intersecting curves is conjugate when the above condition is satisfied at every point of intersection. In partial illustration of the foregoing definitions it may be remarked that all the points of a hyperbola are hyperbolic, and that the right-line generators are its asymptotic lines. On the anchor-ring surface, i.e., the surface generated in rotating a circle about a line in its plane, the curves described by $A$ and $B$, the extremities of the diameter parallel to the axis of rotation, are curves of parabolic points; the inner surface of the ring is the region of hyperbolic points, the outer surface the region of elliptic points. The generating circle is in every position a line of curvature. It remains to define an umbilic as a point at which the indicatrix is a circle.

14. Isothermal Lines. Minimal Lines. Geodesic Lines.—Curvature — Circles — Co-ordinates.—If the $ds^2$ of a surface assumes the form

$$ds^2 = a(u, \psi) \left[ du^2 + dv^2 \right],$$

where $E = G = a(u, \psi) F = 0$, the parameter curves $u = \text{constant}$, $v = \text{constant}$, form an isothermal system (or isometric system) of curves. The parameters $u$ and $v$ are called thermal parameters. The distinguishing par-
erty of isothermal lines lies in this, that by their means the surface can be divided into a network of infinitely small squares. The division is effected by giving to \( u \) and \( v \) series of values in arithmetical progression, the curve series having the same common difference (\( du = dv \)). The squares differ, in general, in magnitude. There is an infinity of isothermal systems on a surface, for the characteristic form (\( \ell \)) is reproduced in new parameters \( u, v \), by making the substitutions
\[
\begin{align*}
u' + iv' &= f(u + iv), \\
u - iv &= f_1(u - iv),
\end{align*}
\]
where \( f \) and \( f_1 \) are conjugate functions but otherwise arbitrary.

It is noted that (\( \ell \)) may be thrown into the form
\[
ds^2 = a(u, v) [(du + iv) (du - i dv)]
\]
and, hence, by the substitutions \( u = u + iv, \mu = u - iv \), an equation of second order. From the theory of these equations (see Equations, DIFFERENTIAL) it follows, that an infinity of geodesics may be drawn at any point of a surface, each determined by its direction at the point.

The expression for \( ds^2 \) takes a notable form when the parameter lines, \( v = \text{constant} \), are geodesics and the parameter lines, \( u = \text{constant} \), are their orthogonal trajectories. Two cases are of interest:

1. The geodesic parallel system, in which the geodesics are drawn perpendicular to an arbitrary curve \( c \) as shown in Fig. 6, and \( t \), \( t_1 \), \ldots \( t_n \), are the orthogonal trajectories. Any two trajectories intersect equal lengths on the geodesics, and it is from this fact that the trajectories derive their name of geodesic parallels. If \( u \) represents the distance from \( c \) to a geodesic parallel measured on the geodesics, into the form
\[
ds^2 = G dt^2,
\]
where \( G \) is a function of \( u \) and \( v \) satisfying two conditions at the pole point:
\[
\sqrt{G} = 0, \quad \frac{\partial \sqrt{G}}{\partial u} = 0, \quad \frac{\partial \sqrt{G}}{\partial v} = 0.
\]

We mention, finally, a system of references in which the curves are geodesic ellipses and hyperbolas. If a point \( P \) moves so that the sum (difference) of its geodesic distances from two arbitrary curves \( c \), \( c_1 \) of the surface is constant, it describes what is called a geodesic ellipse (hyperbola); \( c \) and \( c_1 \) must not be geodesic parallels. Weingarten has shown that the system of geodesic ellipses and hyperbolas is orthogonal. A special case is when \( c \) and \( c_1 \) reduce to points. Liouville has investigated a class of surfaces on which there is an isothermal system of geodesic ellipses and hyperbolas. The form of the arc element is
\[
ds^2 = \left[ f(u) + g(v) \right] (du^2 + dv^2),
\]
and the differential equation of the geodesics can be integrated and brought to the form
\[
\int \frac{du}{\sqrt{f(u)}} = \int \frac{dv}{\sqrt{g(v)}} = b, \quad \text{where} \ a \ 	ext{and} \ b \ 	ext{are constants of integration}.
\]
second order and surfaces of rotation belong to the Liouville surfaces. Gauss established the theorem that the sum of the angles of a geodesic triangle (the sides are geodesic lines) is greater than, less than, or equal to, \(\pi\), according as the triangle lies in an elliptic, hyperbolic or parabolic region. The only surface that can contain an area of parabolic points is a developable surface (see 16), i.e., a surface developable upon a plane.

15. Representation of One Surface upon Another Surface. Conformal Representation. Applicability.—In map drawing one has an instance of the depiction or representation of one surface upon another. To each point of one surface corresponds a definite point of the other surface. The character of the depiction is a matter of the law of relation of the corresponding points of the two surfaces. If the equations of a surface \(A\) are expressed in parameters \(u, v\) and those of surface \(B\) in parameters \(\xi, \eta\), any equations \(u = g(\xi, \eta), v = h(\xi, \eta)\) will give a law of correspondence of points, provided that to a pair of values of \(u, v\) there corresponds a pair of values of \(\xi, \eta\), and conversely.

When each infinitely small triangle on the one surface is depicted in an infinitely small and similar triangle on the other surface, the depiction is said to be conformal. It follows that corresponding angles on \(A\) and \(B\) are equal; also that of \(A\) measured from a point \(P, ds\) the corresponding arc length on \(B\) and \(k\) a quantity depending on the position of \(P\) and independent of the direction of \(ds\). The analytical side of conformal representation is completely resolved by recourse to thermal parameters. The arc element of \(A\) in the thermal parameters \(u, v\) is \(ds^2 = a(du^2 + dv^2)\); similarly, arc element of \(B\) in the thermal parameters \(\xi, \eta\) is \(ds^2 = \beta (d\xi^2 + d\eta^2)\). The relations \(u + iv = f(x + iv), u - iv = f(x - iv)\), where \(f\) and \(\beta\) are arbitrary conjugate functions establish a conformal representation, since, by virtue of these relations, \(ds^2 = kds^2\). Any two surfaces can, in general, be conformally represented upon each other in an infinity of ways. The functions \(f\) and \(\beta\) can be chosen to furnish the most advantageous conformal representation.

Two surfaces are applicable or developable upon each other if the corresponding infinitely small triangles are equal in all respects. This requires that corresponding arc elements shall be everywhere equal, namely, that \(u_i\) and \(v_i\) shall be such functions of \(u, v\) as to transform the first member of the equation

\[
Edu^2 + 2Fdudv + Gdv^2
\]

into the second member. The letters with subscripts indicate the elements of the second surface. In general, this transformation cannot be made, and hence two arbitrarily given surfaces are, in general, not developable upon each other. It is obvious that all surfaces derived from a given surface by bending without stretching (see 8) are applicable upon each other. Hence the parameters of any one of these are applicable in the parameters of the original surface. All the surfaces may, accordingly, be assumed definite in the same parameters \(u, v\), whence it follows that the fundamental magnitudes \(E, F, G\) will be identically the same for the entire series of surfaces. The three magnitudes \(E, F, G\) and all functions formed from them and their partial derivatives are invariants of bending. Some important conclusions can immediately be drawn from these statements. We observe that the left-hand member of equation (\(\gamma\)) is the Gauss measure of curvature and that the right-hand member is a function of \(E, F, G\) alone. We conclude that the Gauss curvature does not change in any deformation of a surface by bending. One notes also that equation (\(\rho\)) depends only on \(E, F, G\), whence the theorem that a geodesic curve remains a geodesic in the deformation by bending.

As earth-dwellers the most interesting depiction to us is that of a sphere upon a plane. The sphere is not developable upon a plane and, therefore, any depiction is bound to be a distorted image of the original. A conformal representation will at least preserve angles, and the picture and original will be similar in the corresponding infinitely small parts. The two best-known examples of a conformal representation are the stereographic projection (Hipparchus, Ptolemy) and the projection of Mercator. Expressing the sphere of radius one in thermal parameters \(u, v\):

\[
x = \frac{2u}{u_i^2 + v_i^2 + 1}, y = \frac{2v}{u_i^2 + v_i^2 + 1}, z = \frac{u_i^2 + v_i^2 - 1}{u_i^2 + v_i^2 + 1}
\]

and a plane in thermal parameters \(u, v\): \(x = u, y = v\); the stereographic projection is furnished by the relations \(u + iv = u, u - iv = v\). For the Mercator correspondence one sets up the relations \(u_i + iv = u, u - iv = v\). Or \(u = u_i \cos \psi\), \(v = v_i \sin \psi\). In the stereographic projection the circles of the sphere are represented by circles (or straight lines) in the plane; in the Mercator map the meridians and parallels of latitude appear in the plane as a system of orthogonally intersecting right lines.

16. Ruled Surfaces.—The continuous motion of a straight line through a simple infinity of position generates a ruled surface. When the consecutive generators intersect, that is, when the generating line is always tangent to one and the same space curve, the surface is a developable surface. In the contrary case the surface is called a skew surface. The director cone of the ruled surface is formed by drawing through an arbitrary point of space lines parallel to the generators of the ruled surface. The equations of the most general ruled surface are

\[
x = a_1 + \beta_1 u, y = a_2 + \beta_2 u, z = a_3 + \beta_3 u
\]

where \(a_1, a_2, a_3, \beta_1, \beta_2, \beta_3\) are functions of \(v\) alone. The curves \(v = \text{constant}\) are the right-line generators; the curves \(u = \text{constant}\) are trajectories of the generators. The trajectory \(u = 0\) is sometimes called the director curve. The important elements are: (1) The angle \(d\) between two consecutive generators \(g_1\) and \(g_2\); (2) the shortest distance \(d\) between \(g_1\) and \(g_2\); (3) the value of \(u\) corresponding to the point,
SURFACES, THEORY OF

called central point, where the shortest distance meets \( a \). Putting for brevity
\[
B_1 = B_d B_3 - \beta d B_1, \quad B_2 = B_d B_3 - \beta d B_2, \\
B_3 = B_d B_3 - \beta d B_3,
\]
the values are
\[
ds = \sqrt{B_1^2 + B_2^2 + B_3^2}, \quad \beta_1, \beta_2, \beta_3
\]
\[
\frac{\partial}{\partial \beta_1}, \frac{\partial}{\partial \beta_2}, \frac{\partial}{\partial \beta_3}.
\]

The locus of the central points of the generators is a curve called the line of striction.
Its equation is the third of the group above.
For a developable surface \( \beta_1 = 0 \). The surface is cylindrical if \( B_1 = B_2 = B_3 = 0 \). The tangent plane to a skew surface at a point contains the generator through the point, and the plane rotates about the line as the point of contact moves on the line. The normals of the surface along a generator form a hyperbolic paraboloid. A ray may be made to move under a deformation by bending so as to remain a ruled surface. The developable surfaces are so named because they are developable upon a plane. Their linear element \( ds \) admits of being thrown into the form of the \( ds^2 \) of the plane.

17. Surfaces of Constant Gauss Curvature.

These surfaces are of three kinds: (1) Surfaces of constant positive curvature for which \( K > 0 \) or \( \frac{1}{\beta_1} \) is positive and constant at every point.
The sphere is the type of this class. (2) Surfaces of zero curvature for which \( K = 0 \) at all points. These are the developable surfaces (see 16) of which the plane is the type. (3) Surfaces of constant negative curvature, \( K < 0 \), of which the pseudosphere is the type.
The pseudosphere is the surface generated by rotating a tractrix about its asymptote.
Minding showed ("Crelle's Journal für Mathematik, 19, 1839") that all surfaces of the same constant curvature are developable upon each other, and in \( \infty \) ways. The geometry of figures on a surface of constant positive curvature may, therefore, be studied on a sphere; that of developable surfaces on a plane; and, finally, the geometry of surfaces of constant negative curvature is identical with that of the pseudosphere. All surfaces of constant negative curvature are called pseudospherical surfaces. In employing a geodesic polar system of reference (see 14) the \( ds^2 \) of pseudospherical surfaces with measure of curvature
\[
-\frac{1}{K^2} \text{ takes the form } ds^2 = du^2 + R^2 \sin \frac{u}{R} dv^2.
\]

A characteristic distinction between the geometries of the three kinds of surfaces of constant curvature is indicated by the number of geodesics that may be drawn through a point parallel to a given geodesic. On a pseudospherical surface two parallels may be drawn; on a developable surface only one parallel; on the surface of positive curvature, none.

18. Minimal Surfaces. — They are defined to be the surfaces of mean curvature zero, \( H = 0 \) (see 12). At every point of such a surface \( R_t = -R_n \). Historically the theory of these surfaces had its origin in Lagrange's investigation of the surface of minimal area with prescribed boundary curve. It was ascertained that for such a surface \( R_t = -R_n \) but the converse statement does not always hold without limitations. Integrations of the differential equation of minimal surfaces were given by Legendre, Monge and others. We give here the equations as found by Weierstrass:
\[
z = \frac{1}{2} \int (1 - u^2) F(u) du + \frac{1}{2} \int (1 - v^2) F(v) dv,
\]
\[
y = \frac{i}{2} \int (1 + u^2) F(u) du + \frac{i}{2} \int (1 + v^2) F(v) dv,
\]
\[
s = \int u F(u) du + \int v F(v) dv.
\]

\( F \) and \( F_i \) are concurvate functions of the conjugate complex variables \( u \) and \( v \). All minimal surfaces are contained in these formulas. When the function \( F \) is algebraic the surface is algebraic, and conversely. A minimal surface can be deformed by bending so as to remain a minimal surface. For this it is necessary and sufficient that one replace \( F(u) \) and \( F(v) \) by \( \varphi(u) \) and \( \varphi(v) \), respectively. All the surfaces corresponding to values of \( a \) (real constants) are developable upon each other as having the same \( ds^2 \). The only ruled minimal surface is the ordinary helicoidal surface with director plane. The only minimal surface of rotation is the catenoid, i.e., the surface generated by rotating a catenary about its base. These two surfaces are developable upon each other. The minimal surface is the only surface (aside from the sphere) whose spherical representation is conformal (see 12 and 13). For particular as to these surfaces consult Schwarz, "Gesammelte Mathematische Abhandlungen" (Vol. I, 1890); Darboux, "Leçons sur la Théorie Générale des Surfaces" (Vol. I, 1887).

19. Concluding Remarks. — In addition to the special surfaces here described may be noted the surface of centres, i.e., the locus of the centres of curvature of a given surface. It consists of two sheets \( S_i \) and \( S_j \) corresponding to the two centres of curvature at every point. Also may be noted the \( W \) surfaces or Weingarten surfaces, in which \( R_1 \) and \( R_2 \) are functionally related. A functional relation, \( f(R_1, R_2) = 0 \), defines an infinity of surfaces. In passing to the surface of centres of individual such a group, Weingarten showed that all the sheets \( S_i \) are developable upon each other and upon the same surface of rotation. The same theorem holds for curves for the sheets \( S_j \). Surfaces of constant curvature, and minimal surfaces are special \( W \) surfaces. Finally, there are certain analytical expressions constructed in the fundamental magnitudes, some arbitrary functions, and derivatives of the functions, which have the same value whatever the parameters employed. In particular, quantities invariant with respect to a change of parameters. When the arbitrary functions are present they are called differential parameters. When the arbitrary functions are not present they are called differential invariants. Manifestly these magnitudes are connected with those geometrical properties that are essentially independent of the particular system of parameter reference. For example, Gauss curvature
\[
-\frac{1}{R_1 R_2 R_3}
\]
is obviously an invariant.

Bibliography. — Some of the principal treatises on the theory of surfaces are Darboux,
SURGEON IN ARMY AND NAVY OF UNITED STATES—SURGERY

JAMES MACLAY,
Professor of Mathematics, Columbia University.

SURGEON IN THE ARMY AND NAVY OF THE UNITED STATES. The history of the connection of a regular staff of surgeons to the army dates back to the siege of Boston in 1775. At that time the Second Provincial Congress of Massachusetts Bay was in session and on 8 May 1775 appointed a committee to examine such persons as are or may be hereafter surgeons for the army now forming in this colony. Of the 16 candidates examined only six were rejected. On 21 July 1775 Washington urged in a letter to the Continental Congress that a 'Hospital Department be established,' and on 27 July this department was created, having a director-general, chief physician and 20 surgeon's mates. In April 1776 Congress passed an act that the board of surgeons be increased 'not exceeding one surgeon and five mates to every 5,000 men to be reduced when the army is reduced.' Between 1784-89 no medical department was officially recognized by the government, but was in the latter year recognized and remained the same until 1821, when it took the form which it retained with no decided change until 1908 when the titles of all medical officers, excepting the surgeon-general of the army, became the military rank, major, captain, etc., followed by the words, Medical Corps, U. S. A. Applicants for the medical corps must be between 22 and 30 years of age, be citizens of the United States and graduates of a reputable medical school and must have had at least one year's hospital training. After successful examination they are commissioned as first lieutenants. The Act of 1908 also established the Medical Reserve Corps, the members of which rank as first lieutenants and are appointed by the President after an examination. During the Civil War and the Spanish-American War the corps was increased to meet the emergencies, but on the cessation of hostilities was again placed upon a peace footing. Consult Lamphere, 'United States Government' (Philadelphia 1880); Farrow, 'Military Encyclopedia' (New York 1885); Hambley, 'Army and Navy Register' (New York 1888) and other War and Navy Department records. See United States, Army of the; United States, Navy of the.

SURGEON-FISH, a fish of the family Trichiuridae, allied to the butterfly-fishes (q.v.) and distinguished by the presence of one or more dark bands running like a belt from the forehead and the root of the tail which may inflict an ugly wound. Some 80 species are known, mostly of the genus Trichiurus, scattered through the warm seas of the world and variously known asdoctorfish, lancet-fish, tunny and among the Spanish-speaking fishermen of the West Indies as barberos and médicos. All are oblong, compressed, brownish or bluish fishes from 6 to 12 inches long, with narrow protruding incisor-like teeth. Several are good food, especially the ocean surgeon-fish (T. bohunus) found throughout the West Indies, and the blue tang (T. carolus), found near Porto Rico.

SURGERY. History of General. The history of medicine, fascinating at all times, is most valuable to the surgeon when applied to the subject of general surgery. At the present time there is much in the literature of medicine that is very instructive and it becomes more and more so as we are put in possession of facts pertaining to prehistoric man and of those presented in the study of manuscripts antedating the Christian era.

Skulls of the prehistoric period have been discovered in caves and dwelling-places which show undoubted evidence that trephining had been performed on them and that healing of the bone had later taken place. The examination of these specimens is exceedingly interesting. Again, as we study the man of this age and the beginning of the Christian era we note a great deal that leads to the conviction that surgery was understood in those times. The early embalmers, in their familiarity with the human body, must have acquired some knowledge of surgery, and this as far back as 1700 B.C.

While medicine as a profession was confined to the duties of the priest, surgery suffered, and was more and more neglected. Historians of that time have just reason to condemn Egyptian surgery. There are some very excellent books appearing at the present time giving a full description of what little was known, bestowing full credit upon those who practised surgery, or advocated it, and who were making some progress in that branch of medicine. The Egyptians were proud and fond of their work as scribes or writers, their learning in that direction leading them to advise their sons to take up what was then known on the subject of medicine; but very little seems to have been developed in the way of clinical observation, or, more particularly, in surgical procedure.

In the study of medicine by the Hindu one cannot but note that in their writings there is plain evidence that surgery had reached an advanced stage. *Surgery,* says their great Susruta, is the first and highest division of the healing art, least liable to fallacy, pure in itself, perpetual in its applicability, the worthy produce of heaven, the sure source of fame on earth. He also makes the very excellent observation that he who knows but one branch of his art is like a bird with one wing. This writer was a very careful observer and beyond doubt did much to advance the art of surgery centuries before the birth of Christ. Some of the Hindu works and operations are yet spoken of by modern writers. They knew how to perform successfully the operation of developing a new nose by flaps taken from the face, and were familiar with these procedures. The surgery of ancient India is worthy our most thorough and careful investigation. Great interest is being manifested in its study and there can be no doubt that it will result from the recent organization of the Charaka Club in
New York. This body of investigators bids fair to give us papers of great value in the elucidation of that period when Hindu surgery developed—and, it may be said, ceased. Why it disappeared so mysterious ly has never been shown.

Through the study of manuscripts of succeeding centuries, and of other records of different peoples, one is greatly impressed with the difficult operations performed, now and then, by some predominating man, who, perhaps having more knowledge of the anatomy of the human body, and being somewhat bolder than his fellows, would perform an operation, leaving a report of possible success. Then for centuries this work would be forgotten, then revived, perhaps modified. Possibly to the operator it was a new operation (since he was not aware that it had been performed previously), yet to be developed into a line of work that was to lead to greater success. Thus we see reported very important advances in the line of surgical procedure from our earliest knowledge on.

The early Greek knowledge of surgery is not so apparent or abundant as that of later periods. Yet this primitive medicine gives endorsement to the fact that there were surgeons capable of rendering aid in emergencies, such as the removal of foreign substances from the body, and who were able to control bleeding by the application of what were evidently understood to be drugs possessing some styptic power and to bind up and dress wounds. Even fractures and dislocations were treated. In time of war these men were looked upon with reverence and the aid they were expected to render was highly valued. Of their real work there is little known before the Trojan War. The most observing student of cases in antiquity was Hippocrates (q.v.) born 460 B.C. He wrote on the treatment of articulations, luxations, fractures and also on the subject of the use of instruments, but his knowledge of anatomy must have been very meagre. The Greeks had great respect for their dead, which prevented dissection of the human body. They knew nothing of physiology and, therefore, anatomical structures such as arteries, veins, nerves, tendons, ligaments and membranes were hopelessly confused. Hippocrates gave classifications not unlike those of the present day, "internal medicine" and "external or surgical medicine," which were convenient, but not philosophical. The period of his life marked the transition from mythology to history. His doctrine and clinical observations were received with great respect. He advanced the science and art of surgery, but only a little later ignorance again reigned in the school which he made celebrated.

Erasistratus (about 300 B.C.) was a close observer as an anatomist and made use of his knowledge of physiology. He discovered the lymph vessels, described the epiglottis, successfully removed the spleen and performed other remarkable operations.

Aretaeus was one of the most brilliant men of the second century before the Christian era. He introduced surgical aftercare of the brain and described the Syriac or Egyptian ulcer, tetanus and anal fistula.

Galen (q.v.), who died about 201 A.D., must have had considerable knowledge of anatomy. History indicates that he was a vivisector, and to him is due a clear classification of the muscles, which is followed at the present day, as the "flexors and extensors." He came very near discovering the circulation of the blood, and divided the body into the "cranial, thoracic and abdominal cavities," whose proper viscera and envelopes he described. This was during a period when encouragement was given to the study of anatomy. The works of one Orissors (q.v.), who died about 400, were based on the writings of those who had preceded him, but had a distinct importance of their own. He showed much originality in the treatment of hydrocephalus, advised paracentesis of thorax and abdomen, removal of vesical calculi, treatment of aneurism, excision of hypertrophied mammae in men, etc. Antyllus who flourished about this period was one of the most distinguished and original surgeons of antiquity. He was the first to describe the extraction of small cataracts and is perhaps best known to the surgical world of to-day by his beautifully bold plan of opening aneurisms, so successfully imitated by the late James Symes.

It is to be remembered that during the Greek period Galen and his followers dissected animals and occasionally a corpse on the field of battle.

In the 6th and 7th centuries the Arabians gave more encouragement to dissection and demonstrated that surgery required a knowledge of anatomy. One of the most celebrated Arabian physicians was Rhazes (q.v.), who died about 932. He compiled from the authors some 37 books on medicine and surgery.

Albucasis (936-1013) in one of his writings gives a most detailed account of necessary instruments and in speaking of their proper use and application to surgery, he emphasizes the fact that surgeons should be versed in the science of anatomy.

In visiting the various museums in Europe at the present time, especially Naples, one is greatly impressed with the variety of ancient surgical instruments that have been recovered from the ruins of Pompeii and other former surgical centres.

Avenzoar (q.v.), who died about 1169, wrote one of the most remarkable treatises on renal diseases, especially in reference to the treatment of calculi and further surgical intervention.

From the 9th to the 13th century the Jews and the Christian clergy shared the honors of the healing art, and during this time references are not infrequently made to the work of the barber-surgeon (see BARNES). Lithotomy (q.v.) seems to have been developed in this period and it is noted (1022) that Henry II, Holy Roman emperor, was cut for stone by Saint Benedict himself.

In the 13th century Rolger of Palermo was evidently one of the most distinguished pioneers in modern surgery. He was the first to use the term "seton." His pupil, Roland, wrote a treatise on surgery, which became very famous and was mentioned by Guy de Chauliac, the "restorer of French surgery in the 14th century." The latter was probably one of the most famous surgeons of that time. He opened the abdomen for dropsy and operated for the radical cure of hernia and for cataract.
The history of the school of Salerno in the 13th century indicates that plastic surgeons had to devote a certain time to the study of anatomy, were obliged to pass an examination by the faculty of the university and were licensed by the royal hands. Surgeons recognized the importance of nausea, vomiting and hemorrhage from the ears, in injuries to the head. They used the trephine (q.v.) in treating fractures of the skull and treated hernia cerebri by pressure and caustics. Ligatures were used in wounds of the carotid arteries and jugular veins. The surgeons also treated wounds of the abdomen. Lithotomy was described with care and compound fractures were treated with splints.

The first important work on minor surgery appeared during the 14th century. It was written by Lanfranc, but although it grew into a second and larger treatise, surgery soon after this began to decline. The barber-surgeons of this period were possibly the first to impress upon the profession the importance of searching in the cadaver for the concealed cause of disease. His observations on gall-stones and conveyance of syphilis from the mother to the fetus were original.

Notwithstanding the progress in surgical science during the 15th and 16th centuries, the practice of surgery was largely abandoned to a class of ignorant barbers and bone-setters. Most of these operators traveled from city to city, individual practitioners limiting themselves to operations on stone or for hernia. This condition of affairs, together with the prejudice against dissection, was most unfavorable for the profession of surgery.

France at this time presented the only special college for the instruction of surgeons. To the 16th century belongs the career of the most wonderful surgeon, Ambroise Paré. He was an original thinker, had the courage of his convictions and did away with the use of the cautery and boiling oil in amputations, using ligatures to control hemorrhage, the latter being the most important advance until the introduction of ether in 1846 (see ANESTHETICS). At the beginning of the 17th century surgery reached a higher social and intellectual plane than it had heretofore occupied. Amphitheatres for dissection developed in many European cities, together with hospitals and dispensaries in connection with the various schools. The term inflammation was then introduced and from that time until the present day has been a subject for continuous investigation. From this time surgery may be dated. The beginning of consultation work between expert practitioners; and clinical teaching and the presentation of surgical cases then advanced their claims. Surgical history from Valsalva on presents the names of many who became eminent operators, and in their writings did much to advance the art of surgery. Notably was this to among the Italians, who in their plastic surgery developed the Italian method for construction of a new nose.

In France, Morel (1674) invented the tumniquet, Denis performed the first transfusion of blood in man and other French surgeons became very expert in the operation for lithotomy. Mareschal (1658-1736) had a record of eight lithotomies performed in half an hour. He was one of the founders of the French Academy of Surgery.

In Holland, Rau (1658-1719) taught practical surgery upon the cadaver. Wiseman (1625-86) was the first to develop English surgery. He was also the first to do external urethrotomy for relief of stricture. At this time in France alone was instruction in surgery well regulated, as it was the only country which possessed a proper surgical college.

In the 18th century hospitals began to multiply in Germany, benefiting general surgery to a great extent. Brasted (1711) described the method of distal ligation of aneurisms, while Sabatier (1732-1811) wrote a treatise on operations and recommended resection of the head of the humerus. Desault and Chopart did much in developing operative surgery. In Italy Scarpa (1752-1832) advanced our knowledge of hernia and aneurisms. Spanish surgeons did little to improve the science and art of surgery. In England, Cheselden (1688-1752) did much in advancing the knowledge of pathology and general surgery. White, of Manchester, designed a method of reducing dislocations of the humerus with the foot in the axilla. A well-defined operation for excision of the joints was also first practised in England. The investigation of pathology and diagnosis in France at this time had much to do in the 19th century in developing the *new Vienna School*. Percival Pott (q.v.) did much in elaborating and classifying diseases of the joints and especially spinal diseases. John Hunter (q.v.) was the most famous English surgeon of his day. He belonged to a family which in many ways assisted the development of pathological anatomy and surgical technique. At the close of the 18th century, Benjamin Bell was the first to make use of drainage by means of tubes of lead or silver. In France, Bichat (q.v.), although not generally so understood, became a forceful lecturer on surgery and did much to bring hospital-gangrene under observation and control. The Dutch during the 18th century developed some eminent surgeons, and it is interesting to note how dextrous they became in the use of instruments. At the same time their knowledge of anatomy enabled them to present some very able papers on the subjects of hernia and dislocation. Sandifort, of Leyden, first described a downward dislocation of the femur.

In reference to the surgery of our own country in the 18th century, one of the most interesting works, which was of great service to American surgeons, was that of John Jones, *Plain, Practically Precise Remarks on the Treatment of Wounds and Fractures.*

The 19th century witnessed great advances and from 1838 was one continuous chapter of investigation toward the development of the
parasitic or germ theory. Of all the many names associated with this immense work, one can refer to but few: Pasteur, Klebs, Koch, Lister, Tyndall (q.v.) and others, in their development of bacteriology, have done more to advance the principles of technique in surgical operations and have placed the art and science of surgery upon a more lasting foundation, than any of their predecessors.

The first half of the 19th century was a period of great success for the French surgeons. The English surgeons, in their superior knowledge of gross anatomy, also made great advances in their diagnosis and surgical treatment. This century became noted as the period during which general surgery developed more into an exact science. Its writers did much to eradicate erroneous ideas and to end the transmission of meaningless sentences from one textbook to another. The introduction of anesthesia in 1846 enabled some of the bold men to perform operations heretofore deemed quite impossible and the rate of mortality was reduced from 60 to 6 per cent, and this ratio was soon applied to all departments of surgical work. As technique became more perfect, all manner of operations were suggested and carried out with great success. Hence to-day there is no part of the human body that the surgeon is unable to reach for the relief of injuries or pathological conditions.

In operative surgery much help has been received from the use of cocaine, eucaine, suprarenal extract, ethyl chloride and other preparations for local and spinal anesthesia. Bacteriology has taught the surgeon the cause of inflammation, suppuration of wounds and sepsis. New hospitals, aseptic operating-rooms and furniture, thorough sterilization of instruments, bands and the field of operation and cleanliness of person, together with the wearing of rubber gloves, coupled with aseptic dressings, have enabled the surgeon to perform operations unknown before the last decade of the 19th century, and in a short time reduced from 60 to 6 per cent, and this ratio was soon applied to all departments of surgical work. As technique became more perfect, all manner of operations were suggested and carried out with great success. Hence to-day there is no part of the human body that the surgeon is unable to reach for the relief of injuries or pathological conditions.

During the 19th century the microscope became of more and more value. The anthrax bacillus was classified in 1850 and then followed classification of the various micro-organisms known to-day. Koch's identification of the tubercle bacillus has aided the general surgeon as much in the treatment of osseous tuberculosis as it has the physician in tuberculosiis in other parts of the body.

In the past two decades general surgery has presented a mass of material, largely experimental, and much of it bacteriological and pathological. The latter has assumed a better position because of some real practical discoveries, but the former has brought about a large lifting out of much that was thought of great value, experience, however, demonstrating to the contrary. Let us consider the treatment of fractures. The various methods of plating and suturing, by means of silver wire, have had very strong advocates, yet in the use of splints, extension and position have retained their well-recognized effectiveness. There would seem to be a consensus of opinion that when the X-ray shows the fracture has been reduced and the parts brought into a fairly normal position, these cases do fairly well without operative intervention; however, when the positions are faulty, and, even though an anesthetic is employed, reduction cannot be accomplished satisfactorily, there can be little doubt that they do very much better and more perfect results obtained, by operative procedure. It is now becoming recognized the fractures of the clavicle and other irregular bones demand operative intervention, by employment of plates and like methods.

The knowledge of the anatomical relations of the various joints, especially that of the hip and shoulder, with the aid of X-ray, manipulation, becomes more perfect and more reliable in results.

In dislocations the X-ray has continued to demand greater employment because of its worth.

In the past 10 years it is pleasing to observe that the methods of scientific X-ray work have become very much more extensive and precise; that the X-ray apparatus, in examinations of the head, thorax, abdomen, pelvis and extremities, greater precision has been reached and the results much more reliable and satisfactory; that in the understanding of the location of foreign bodies, much has been accomplished in reading the shadows correctly.

It is in the diagnosis of fractures and dislocations that there has been a steady, continuous improvement. This observation becomes very appropriate when referring to lesions of the spinal column and surgery of the spinal cord.

This knowledge also applies to the better understanding of pathological conditions, especially within the abdomen and the location of stone in the kidney and bladder; however, this must be said, that in the past few years physicians, surgeons and specialists have come to recognize the Roentgenographer as the one alone who can interpret the radiograms and make it clear to the surgeon who is responsible for the case, when an operation is undertaken. In the past it has been too much the custom for the attending medical man to translate the X-ray picture himself and many errors have occurred in that way. This is especially true in reduction of dislocations.

Operations upon the head and teeth, due to the study of X-ray work, have become much better understood, the classifications calling for such procedure much more reliable and showing more and more perfect results.

Comparatively recent parasology has demonstrated that septic teeth have much to do with the development of many surgical lesions, in the past overlooked, and, which, like the tonsils, frequently become the bed for the introduction of pathological micro-organisms into the system.
There has been added to the history of general surgery a very interesting chapter on the treatment of phlegmons and inflammatory septic conditions, by employment of the method known as passive hyperemia. When promptly and effectively made use of it is of great value in cutting short infective invasion of the lymphatic system, especially when applied to the extremities.

The treatment of malignant disease by means of serums, especially Coley's fluid, maintains a semi-successful position, but, considering the length of time it has been employed, it would seem as though it ought to have offered more encouraging results.

The same applies to X-ray treatment, advocated by some so earnestly in its use previous to, and after, an operation for relief of malignant troubles, yet not establishing itself as a positive curative agent.

The range of general surgery is becoming so great, the multiplicity of theories and papers proposing such new and seemingly superior methods so great, that one can hardly hope to make any great contribution to the methods of diagnosis and treatment that may be said to be final and the results such as to command the confidence and respect of the operator. The history of modern methods, regarding general surgery, in pathology and diagnosis, through bacteriological, laboratory work, is wonderfully encouraging, but much more time is required than was made use of by the surgeons of a somewhat receding and later date, in their examination of cases.

The thorough study of the blood, bacteriologically and otherwise, the vaccines, are all to be considered in the present history of surgery and proving elements of great importance. This applies to all modern surgery, reaching all points that have developed through research work and of great use in the study of general surgery to-day.

In the study of the history of general surgery, the many papers that are presented in our medical journals, also in our textbooks, from year to year, it is to be observed that advances are being made in the methods of diagnosis and proper treatment. There is this constant evidence that exploitation of supposed new discoveries, in their proper relation, have failed to maintain the expected high standard of success, for instance, in appendectomy. At first suggestions for this operation met with a great deal of encouragement in the hope that, as the appendix was permanently fixed in the incision, it could be made the source of successful treatment of pathological changes within the large intestine; however, it does not seem to have found approval to the extent of many cases appearing on record, or employed so extensively as at one time thought possible.

Also, while there have apparently been a few excellent results, yet Edebohls's suggestive treatment of nephritis, by decapsulation of the kidney, does not seem to have sustained the endorsement of the pathologist or the operating surgeon.

In the changes and successes in diagnosis and treatment, during the past decade or two, great progress is to be observed in comparing one period with another — one method with another. That of which so much was expected too often proves valueless, while that which seemed of lesser importance proving of great value, on trial.

In civil life the advances made in surgery of the head, face, neck and thorax, the mediastinal space, the heart, of the lungs and pleura, indicate the calm, steady progress that is now to be observed in all larger hospitals.

Especially does this apply to stab wounds of the heart, to the drainage of abscesses within the pericardium, also in operations upon the lungs and treatment of the pleura for various surgical conditions.

The recent acquisition of the pathology of the thyroid and parathyroids has resulted in the understanding of goitre, far ahead of anything that has ever taken place in the past. The function of these glands, the classification of symptoms and of the pathological condition, has enabled the surgeon to do his work in a more scientific manner and the results much more favorable. The better understanding of the term exophthalmic goitre is exceedingly pleasing in every respect.

In abdominal surgery it is no longer necessary to make use of theories, for practical facts are such that, for instance, in surgery of the liver, gall-bladder, pancreas, gall ducts, the pancreatic ducts, there is now a fixed line of treatment, and not to be deviated from very much. This is becoming more and more positive, and also applies equally well to the appendix.

The surgical treatment of gastric and duodenal ulcer is one of the finest demonstrations of surgery being made more of as an exact science than internal medicine has yet attained.

Injuries and diseases of the pancreas and spleen illustrate much of the advance made in the field of diagnosis and treatment.

The abdominal cavity has come under such thorough observation that the right side can no longer hold its exclusive position regarding operative intervention.

There is no part of this one classification of the human body, and in which Galen was so correct, that is entirely free from possible invasion.

In the past two decades much has been added to our knowledge of intestinal surgery and methods of treatment have reached a more conclusive line of operative procedure.

In civil life no more brilliant results can be shown in any of the various departments of surgery than the treatment of multiple gunshot wounds and ruptures of the intestines and other organs within the abdominal cavity.

This applies particularly to hernia — rupture — and especially for relief of gangrene of the intestine. To the surgeon of many years practice, it is particularly striking to note how few cases we now come in contact with of delayed strangulated hernia, in which we have the complication of gangrene of the bowel. The prompt recognition for early operation in such cases has largely eliminated this catastrophe. Our pathological knowledge is much more clear, also the willingness of the patients to have an early operation, and not trust to mechanical supports. These cases, treated, as they often are, comfortably and palliatively by the applica-
tion of trusses, still continue to present an excellent history in the good results of operative intervention. We see a gradually increased willingness, in fact patients often seek an opinion when the result has been so thoroughly satisfactory. All of this applies as well to children as adults.

In the treatment of conditions within the abdominal cavity, a greater concensus and uniformity of opinion has been reached than in some other surgical channels.

Perhaps we may say there is yet a lack of uniformity in doing the operation of intestinal anastomosis.

Excision of the large intestines seems to have reached the peak of operative intervention, and present results are being studied with great care, regarding curative results in this class of surgery.

Surgery of the appendix gives a very extensive history, upon what has been written in the past, and, now, regarding diagnosis and treatment, becoming very concise. The general practitioner of to-day is more alert than ever in the recognition of early symptoms and prompt surgical procedure. When these methods are yet more thoroughly considered and carried out, the appendix, from the medical and surgical standpoint, will present a mortality much less than exists at present, though this is exceedingly small.

The history of operations done upon the bladder, for various pathological conditions, is a very impressive one. Decided advances have been made in this direction, and the same can be said of the prostate gland, while surgery of the kidney has reached a point of great precision, the same also to be said regarding the ureters.

In all that pertains to the surgery of the abdominal cavity, much has been accomplished through the study of the Trendelenberg and other positions for the patient during the time of operations, especially upon the kidney or gall-bladder and in pelvic work. Much of this also applies to the treatment of the patient after an operation, particularly in suppurative, septile appendicitis, as has so well been brought out by the writings of the late Dr. Fowler.

In the advances made within the abdominal cavity the searching out of every pathological condition, no organ or tissue being overlooked, is one of the most impressive to be noted in the history of general surgery.

Gall-stones have a way of giving a great variety of symptoms, the same applying to cases of appendicitis, and which, perhaps, has brought out many valuable conclusions.

In the history upon one of these organs and not finding a pathological condition that will accord with the symptoms, it is admitted by most surgeons that a more thorough examination is called for, and in some other unsuspected organ may be found the source of the symptoms, relief being afforded only by doing the operation called for in that direction.

Since the last edition of the Encyclopedia Americana much has occurred in the history of general surgery, regarding surgical procedure, to make clearer new fields of observation, and which applies especially to the abdomen and its contents.

The abdomen has claimed much of the attention of the general surgeon. It has not been possible for the specialist to control this line of work. With our increased knowledge of pathological conditions within this cavity, with the aid afforded the operator through the advances made by the assistance of the experienced radiographer, who is able to interpret radiograms correctly, the success has been so great that patients, or their friends, have little hesitation in entering a hospital, or going to the operating table, when the necessity is made apparent to them. Hence in the building of the many smaller hospitals the past few years, local surgeons have developed an experience that permits of doing many operations deemed impossible for them to perform a few years ago.

In the past two decades much progress has been made in surgery of the bones; in the conservation of limbs and joints; in the better understanding of pathological conditions and especially does this apply to cases of malignant and tubercular troubles.

Surgical lesions of the circulatory system have received much attention, and surgeons have had occasion to discuss the subject of idiopathic aneurisms. Operative surgery in the near past has not met with so many of these cases, and the condition is believed to be due to the more successful treatment of syphilis, this being one of the chief factors in development of this lesion.

The subject of inflammation of the veins—phlebitis—has commanded careful investigation in our laboratories, it so often being the factor in connection with sudden death following an important operation. To relieve the blood clot that forms in the vessel, then suddenly separates, enters the circulation, plugging the heart valves and causing sudden death, calls for surgical intervention, when it can be recognized as being present in the large veins of the extremities.

It is also to be observed that a less number of cases of stone in the bladder are presented, due to the better understanding of calculi originating within the calyces, and condition corrected by the study of diet, the drinking of properly selected mineral waters or the careful use of plain sterile waters. Here diet has much to do in lessening the development of many surgical lesions.

The medico-legal side of the responsibility of the surgeon has been pretty thoroughly covered the past few years in the history of malpractice suits for foreign bodies left in the abdominal cavity, with the result that the operator, the hospital, and the surgeon alike the responsibility, and must give evidence of having exercised every precaution possible to avoid such occurrences. Especially is it the duty of the surgeon to have it well understood with the one nearest in relationship to the patient regarding the extent of an operation. If, in the midst of it, it is found necessary to do more than was explained, the operator must communicate with the responsible person regarding the condition present that requires greater operation.

In proceeding to present the results of operation, we find a conclusion why every cautious surgeon desires some person near at hand to inform them, should complications unexpectedly arise.
British surgeons have had some unpleasant experiences in this direction.

Regarding the anesthetic in use by the general surgeon, it may be said that sulphuric ether is undoubtedly employed to a greater extent than any other anesthetic. Chloroform is believed to be advisable in the short operations, and in those upon children, while for those only requiring a few moments the nitrous oxide or ethyl chloride are of great service.

**ALBERT VAN DER VEER, M.D., Professor of Anatomy, 1869-74. Professor of Surgery, 1876-1915, Albany Medical College.**

**SURGERY IN AMERICA.** If at any time one should purpose writing a history of the progress of surgery on the American continent he must not fail to remember that in the earlier part of its history America was absolutely dependent on Europe, and could not be expected to reflect anything better in the direction of science than that which it received from its mother-country. Therefore, the most suitable form could be made for the history of surgery on this continent would be a review of the status of the 17th century in Europe. Very prominent were two or three philosophical systems which had been handed down from previous thinkers. The skepticism of Montaigne, with its final reduction by Bayle to universal doubt or universal credulity, and the supernatural or mystic philosophy of Böhme, sometimes spoken of as the cabalistic or theosophistic, which includes the discoveries of Pascal and Malebranche, were the prevailing systems or methods of thought. In the meantime Bacon had lived and died (1626), who, though he laid great stress on gunpowder and the compass, had but little respect for the discoveries of Copernicus. Zoology and botany were fairly well advanced and had been extended by dissection and by classification. Hooke had discovered the cell, and had founded the cell-doctrine. Kepler and Galileo had been persecuted and had left their discoveries for others to verify. Newton entered the world some years after the date of the first expedition of the Mayflower (1642). Continental Europe had many universities, some of which have been discontinued or merged into others. Numerous academies of science had sprung up in different parts of Europe, and the present British Royal Society was remodeled in 1662 by Charles II. Nevertheless, all kinds of superstition prevailed, alchemy flourished, witchcraft was in full bloom, necromancy was generally practised and the divining rod flourished, and all domestic animals were kept under cover during an eclipse lest they be threatened by dire pestilence of unknown character. In 1628 Harvey had published his work on the circulation of the blood, and in 1608 the microscope had been invented by Lippersheim, although by some its invention is attributed to Jansen in 1620. At all events it was greatly improved by Hooke, who died in 1702. Logarithms were not invented until the American colonies were nearly 100 years old (1690); Newton's theory of air had been established by Toricelli in 1643. Previous systems in medicine were then modified, to be reformed on the modified Paracelsism devised by Van Helmont or the humoral views of Sylvius and Willis. Sydenham appeared upon the scene about the time of the first expedition of the Mayflower, and, until his death in 1689, the larger number of English physicians who came over in his day had been more or less under the influence of his teachings.

The 17th century is important in the history of surgery, since superstition and self-satisfaction gradually gave way to the inductive method and improved habits of observation. Even among the Dutch, who settled new colonies in this country, surgery was considered a divided position, while among the English, French and Germans it had already attained something of this character. These were still, however, the days of the barber-surgeons, who were not considered gentlemen nor fit to associate with gentlemen, who were, for the greater part, an uneducated and illiterate class. The study of anatomy was still pursued with difficulty, the ban of the Church yet covering those who took part in any operation which was accompanied by the shedding of blood. In the earlier times, the French were its mother-country, the Netherlands and France, while still worse was Spain, at the time when the early adventurers or pilgrims from these various countries landed upon our shores and began to make America.

**Colonial History.**—The English colonists brought their physicians with them on nearly all of their expeditions. Thus when Jamestown was founded, in 1607, we hear of one Wotton, or Woolton, who came out as surgeon of the London Company, who was even considered a gentleman among the others of the expedition, whether by courtesy or right it is not known. Walter Russel followed in 1608. Even within that first half-century came the need for some definite laws regulating the practice of medicine, since throughout the colonies quackery flourished to a considerable extent. There was at this time little to attract travelers to this country except the spirit of adventure, which the better educated men possessed in minor degree. Many of the earlier physicians of the colonies were church deacons or politicians or both. Thus Samuel Fuller, who came to Plymouth in 1620, preferred to be known as a deacon rather than as doctor, although he practised medicine faithfully and, for his time, well. John Winthrop, Jr., was not only a physician but a statesman. In 1667 he became governor of the New Haven colony, and he must have enjoyed much repute in England since he became one of the founders of the Royal Society. Up to 1692, 134 physicians had been catalogued as practising in the colonies. The first person executed for witchcraft was one Margaret Jones, who was also a physician.

In the New Netherlands, controlled first by the Dutch West India Company, it was provided in their charter that they should procure a "Comforter for the Sick." The first one of prominence under this provision was Bogaerdet in 1637; later came LaMontaigne, who was both a Huguenot and a physician. Prominent during the middle of the century was one Samuel Megapolensis, who was born in this country and graduated from Harvard in 1657, and then went to Utrecht, where he took his medical degree. He practised in Manhattan both as a physician and preacher. In 1772 a Quaker, George Fox, was traveling with John Jay when the latter
was thrown from his horse and had his neck apparently broken. Fox at once instituted a manipulation by which, apparently, the dislocation of the upper vertebrae was reduced and by which Jay was restored to life. This must be one of the earliest cases of reduction of the vertebra.

When William Penn came to this country he brought with him Dr. Wynn, an accomplished Welshman and probably the most competent man of his profession in America at that time.

The colonies were swept during this century with fierce epidemics of yellow fever, smallpox, scurvy, dysentery and many other diseases, by which the colonists suffered great loss. Those who came over with William Penn numbered about 100, of whom one-third died on the voyage of smallpox. This was perhaps the most terrible scourge of all and was not successfully battled with until Dr. Boylston dared to institute the method of inoculation to which his attention had been called by Mather, who had read of its successful introduction into England from Constantinople by Lady Montague. In this is constituted one of the most interesting episodes in the history of medicine in this country. Pull, who was a father who must have regretted that he had not his mind even after he had lost his interest in the burning of witches. In 1721 he read a paper on Turkish inoculation written by an imbecile, and he had no interest in it. He endeavored to interest various young men, especially a Dr. Douglas, in the discovery and in the method. Failing in this he turned to Dr. Boylston, then of Brookline, Mass., who saw the importance of the method and the ripeness of the occasion. As soon as his purpose became understood he was at once denounced in the pulpits and attacked by the multitudes, and had as his only backer the man Mather, who had not yet lost his authority with the clergy. Opposed, then, by his colleagues and by the clergy in general, and the universal rabble, Boylston had the hardihood to inoculate first his own son and two negro servants, and this only six weeks after the first inoculation was done in Montague’s London, by Maitland. But Boylston lived to reap glory and profit from his intrepidity. The controversy which he aroused had subsided in this country when he went to London, where he found it still raging, and where he again aroused a storm, but eventually triumphed. (This method must not be confused with vaccination, but consists of the actual inoculation of the disease by pus or discharge from the lesions of the patient suffering from the real malady. It is practically the same method which had existed for centuries in the Orient).

A great part of the 18th century was spent in warfare between natives and the newcomers to this country. The Indians were not always active, while the English and French fought more or less continually, the scene of conflict extending from Quebec on the north to the Niagara Frontier on the west and Georgia. In spite of the many opportunities thus afforded for the study of surgery it does not appear that much was done in the way of improvement of older methods or in new discoveries. The wounded soldier of 1776 had but little better treatment than the wounded pilgrim of 1666. There were a few men of such prominence scattered along the coast line in the early and middle part of the 18th century that they deserve to be mentioned, at least by name. Cadwallader Colden was born in Scotland in 1668, and came to this country in 1707, where he was the first doctor in Philadelphia. Here he wrote some of the first medical papers written in this country, particularly on animal secretion. After some years spent in this country he took up his residence in New York, in 1719. He was one of his life an indefatigable student and attained remarkable popularity in his practice. He held numerous public offices and figured rather as a statesman than as a physician. He acquired a large estate up the Hudson and became the intimate friend of Benjamin Franklin, to whom he first suggested the foundation of the American Philosophical Society. He left a large number of writings and correspondence with the most eminent savants all over the world. As the colonies steadily progressed in wealth and size, Charleston became more and more a prominent centre of influence, and here there lived and died during the century a group of five men, namely, Chalmers, Lining, Gardner, Moultrie and Barre, who made valuable contributions to science and achieved unusual distinction. All of these were of Scotch origin save the last, of whom it was claimed that he was the first person born in South Carolina, as well as the first native to receive a doctor’s degree. He was a pupil of Boerhaave, a graduate of Leyden in 1774. He gradually drifted into politics, as did Colden. Lining was perhaps the first American physiologist and published numerous papers in the Transactions of the Royal Society. He also published the first American account of yellow fever, which was the scourge of the century, and which appeared to spread to this country from the West Indies. Moultrie achieved an honorable position. He had a son who was also a doctor, and while both of them attained a high place in the esteem of their fellow-citizens, the death of the father was regarded as a public calamity, after some 40 years of phenomenal activity. Chalmers was the most active of all the others when he came to this country. He made himself generally known as a writer and developed power which would have made him, under suitable surroundings, a rare teacher. Gardner, like Colden, was a man of culture and fine education; in fact one of the most versatile men of his century in this country. He was a Fellow of the Royal Society. To these should be added, perhaps, John Mitchell, an Englishman by birth, who came to this country in 1705 and made a reputation which spread to the centres of learning in the old country. He published a number of essays in the Philosophical Transactions.}

A great event in the medical history of the 18th century was the foundation of the first hospital in this country. This must be duly credited to the energies of Benjamin Franklin, Dr. Thomas Bond and, later, Drs. Shippen and Morton. Bond was born in 1712, in Maryland. After studying for the ministry he went to Europe, whence he returned full of the idea of introducing the hospital system which had proved so advantageous abroad. Though he returned in 1734, not until 1751 were circumstances sufficiently propitious to found
SURGERY IN AMERICA

something more than a mere camp for the treatment of smallpox or a lazaretto for the care of sick seamen. Franklin threw the whole weight of his influence into this movement and finally £2,000 raised by private subscription, added to a similar sum contributed by the colonists, prepared the way for the opening of the Pennsylvania hospital in 1758. After four years of existence in rented quarters, the cornerstone of a new building for that purpose was laid, bearing an inscription suggested by Franklin himself. This institution had an enormous influence in more than one respect, since its foundation had made possible the creation of the first medical school in this country, which became a part of the University of Pennsylvania, and which owes its inception to the study and liberal enthusiasm of Morgan. Although Harvard College was founded in 1636 and Yale in 1701, it remained for this to become the pioneer medical school in the United States. Albany has a somewhat famous history regarding civil and military hospitals.

Previous to the American Revolution it had cared for many sick and wounded. Just before that period, in connection with the French and Indian wars, it had established a military hospital with accommodations for 500 patients. This was in use during the fighting along Lake Champlain, Lake George, Ticonderoga, Fort Edward, Bemis Heights, Saratoga, Schuyler-ville and the campaign of the Revolution. Later, during the epidemic of cholera, in 1832, barrels were erected in the streets; also in the beginning of the Civil War a large hospital was erected, much in the style of the barracks of to-day, and to this were brought the sick and wounded from about Richmond during the fighting under McClellan.

John Morgan began his study during the period of the French and Indian wars. As he came in contact with the foreign surgeons who came over with the English troops, he found his own ability not at all commensurate with his political bent. In 1760 he went to London and studied under the Hunters, and then to Edinburgh, where he came under the influence of Cullen, the Munroes and others, and where he graduated. He next went to Paris and returned to the United States in 1783. He then made a tour of Europe, having the advantage of a personal acquaintance with Morgagni in Padua. Morgan spent five years in his foreign study and upon his return, in 1765, became closely associated with the younger Shippen. The Shippens were a well-known medical family of Philadelphia, and were men of liberal education and social distinction. Shippen had already given private instruction in midwifery and the two men joined hands most heartily in this commendable effort. When the trustees of the college opened the school Morgan and Shippen became professors, respectively, of medicine and surgery. Thus it will be seen that Shippen was the first professor of surgery in this country, and that the first systematic instruction in surgery was given by him in 1765.

The faculty was joined a little later by Benjamin Rush, who became one of the most conspicuous figures of his day, as a professional man, in this country. He was but 24 years of age when he was made professor of chemistry, and he was but 31 years of age when he became a signer of the Declaration of Independence. The gathering war clouds of the Revolution dampened the ardor of all and the large number of men lying on the hospital and medical school was excessively heavy and fell mostly upon the shoulders of three or four men. In 1779 the assembly revoked its charter which was, however, restored in 1783. In this was put an end to the condition of affairs in New York was not much better.

One man, however, stood out pre-eminently as an efficient physician and broad-minded citizen. This was Samuel Bard, whose name deserves to be closely associated with that of Rush. When he returned to this country in 1765, after a period of foreign study, he was inspired with the thought of founding a medical school in his native land. In 1768 he associated with himself, Clossy in anatomy, John Jones in surgery, Middleton in physiology, Rush in chemistry, Tennent in obstetrics, he himself taking charge of the principles and practice of physic. Thus the medical school of King's College was established. This was perhaps the first in this country to distinguish himself as a surgeon. He had been under the best teachers in Europe, and had seen a great deal of military surgery in his day, especially during the French War. He was independent enough to decline to adopt some of the peculiar notions of his colleagues regarding appropriate costumes, but in the end the absurdities which he dispensed with were discontinued by them. He wrote a book for the Revolutionary surgeon, entitled 'Plain, Concise and Practical Remarks on the Treatment of Wounds and Fractures.'

Up to this time, midwifery had been practised by untrained women and it can readily be seen what an advantage it was to have the science of obstetrics systematically taught as it was in both schools above mentioned.

During the six years while New York was occupied by British troops there was a cessation of college activity. The faculty was not a unit in its political beliefs. The declaration of independence came dissensions. Three years after the war the college went on under its new name, Columbia, but with very poor success. A spurt was made again in 1792. In 1807 the New York University of Physic and Surgery was founded and the jealousy and strife prevented its success. Finally, in 1811, a union of the two schools was accomplished under the name of the younger and thereafter the College of Physicians and Surgeons prospered and is to-day one of the leading schools in this country, though again under the ægis of Columbia. Meantime under Bard's influence, the New York Hospital had been founded in 1768 and chartered in 1770. It was in their new building that the Provincial Congress used to meet during the second year of the Revolution; but when the British arrived the hospital was turned into a barracks and Bard and Jones joined the Continental army. A note in 1793 states that the hospital was fully and finally equipped and began its career of usefulness.

The Revolutionary Period.—At the time of our Revolutionary War the science of military surgery was not considered even with the Continental armies the barber-surgeon had a certain place, in which he was almost a menial, and above which he could scarcely raise himself. The English troops were better
equipped in this respect than were the Hessians, for instance, while during the latter part of the war, especially when the French sent some of their best men to this country, our raw and untrained army surgeons came in contact with a better class of men and by whom they were, to some extent, inspired. Nearly all of the prominent medical men, save the Tory physicians of Massachusetts, entered the army or took public service, and in the Massachusetts Provincial Congress of 1775 there were 22 physicians. Both the colonial and general governments dealt very stingily with their medical departments and the professional equipments provided were almost meager. The history of surgery in those days is mostly the history of a few prominent individuals who made it what it became and who deserve to be briefly mentioned. The brothers Joseph and John Warren took a very prominent part during the earlier portion of the war. It was the former who started Paul Revere on his famous ride. He was elected president of the Provincial Congress and just before the battle of Bunker Hill was made major-general of the Continental forces, preferring this office rather than the office of physician-general which he had been offered. He was a man of wonderful spirit of self-sacrifice and, declining his rank, acted as a private, and with musket in hand fought nobly, and was shot dead just at the conclusion of the battle. The younger brother, John Warren, lived to achieve fame and reputation, and transmitted them to a posterity by whom they have been well preserved. He constituted a brilliant contrast to many of the regimental surgeons who had been too often appointed by political influence without regard to attainment. Some regiments were even organized without a surgeon and came into camp without the slightest provision for disease or injury. In 1776 Congress enacted that there should be one surgeon and five assistants to each 5,000 enlisted men. The former was to be paid $1.66 per day and the latter each $1 a day. The reader can imagine the care 5,000 men would receive from six physicians whose services were compensated at this rate. At that time such a hospital was almost unknown and a hospital corps and ambulance drill were quite lacking. But John Warren, then but 23 years old, proved extremely efficient in the organization and completion of, and accomplished a great deal for the improvement of his department. The first surgeon-general of the Continental armies was Benjamin Church, of Boston, who was given the title of director-general and chief physician and was paid $4 per day. Church gave promise of efficiency in his department, but before long was detected in correspondence with the enemy, for which he was court-martialed, imprisoned for one year and allowed to leave the country and probably lost at sea. His place was taken by John Morgan of Philadelphia, already mentioned above. He had the politicians to fight and after a long and arduous struggle, failing to satisfy them, he was dismissed service, although he was finally acquitted of all blame. This was a time of unrest, excitement and suspicion and had Washington himself been a weaker man, he could scarcely have withstood the dissensions and jealousy with which he was continually surrounded. Morgan was succeeded by Shippen, his old associate, who remained in office from 1777 to 1781. Under his guidance the medical department almost prospered and was at least conducted with dignity and great benefit to all concerned. And smallpox, which had been the scourge of the soldiers as well as the people in general, was kept down by the practice of inoculation, which had been generally accepted by nearly all men from Washington down.

From the Revolution to the Civil War.—The most conspicuous monument of American medicine, which practically began with the conclusion of the Revolutionary War, was Benjamin Rush, of Philadelphia (1745-1813), an exceedingly versatile, many-sided, erudite, obstinate, skeptical man, constant only to his religion which he considered to be a professional duty. He was hated by many of those to whom his methods most strongly appealed. He had rare didactic gifts, but his teachings were abused by his students and followers. As a young man he had traveled in Europe and had taken his degree at Edinburg. He had come especially under the influence of Cullen, whose views he had imbibed and later accepted in a modified form. He served two terms in Congress, where the duties of a wonderful spirit of self-sacrifice and, declining his rank, acted as a private, and with musket in hand fought nobly, and was shot dead just at the conclusion of the battle. The younger brother, John Warren, lived to achieve fame and reputation, and transmitted them to a posterity by whom they have been well preserved. He constituted a brilliant contrast to many of the regimental surgeons who had been too often appointed by political influence without regard to attainment. Some regiments were even organized without a surgeon and came into camp without the slightest provision for disease or injury. In 1776 Congress enacted that there should be one surgeon and five assistants to each 5,000 enlisted men. The former was to be paid $1.66 per day and the latter each $1 a day. The reader can imagine the care 5,000 men would receive from six physicians whose services were compensated at this rate. At that time such a hospital was almost unknown and a hospital corps and ambulance drill were quite lacking. But John Warren, then but 23 years old, proved extremely efficient in the organization and completion of, and accomplished a great deal for the improvement of his department. The first surgeon-general of the Continental armies was Benjamin Church, of Boston, who was given the title of director-general and chief physician and was paid $4 per day. Church gave promise of efficiency in his department, but before long was detected in correspondence with the enemy, for which he was court-martialed, imprisoned for one year and allowed to leave the country and probably lost at sea. His place was taken by John Morgan of Philadelphia, already mentioned above. He had the politicians to fight and after a long and arduous struggle, failing to satisfy them, he was dismissed service, although he was finally acquitted of all blame. This was a time of unrest, excitement and suspicion and had Washington himself been a weaker man, he could scarcely have withstood the dissensions and jealousy with which he was continually surrounded. Morgan was succeeded by Shippen, his old associate, who remained in office from 1777 to 1781. Under his guidance the medical department almost prospered and was at least conducted with dignity and great benefit to all concerned. And smallpox, which had been the scourge of the soldiers as well as the people in general, was kept down by the practice of inoculation, which had been generally accepted by nearly all men from Washington down.

From the Revolution to the Civil War.—The most conspicuous monument of American medicine, which practically began with the conclusion of the Revolutionary War, was Benjamin Rush, of Philadelphia (1745-1813), an exceedingly versatile, many-sided, erudite, obstinate, skeptical man, constant only to his religion which he considered to be a professional duty. He was hated by many of those to whom his methods most strongly appealed. He had rare didactic gifts, but his teachings were abused by his students and followers. As a young man he had traveled in Europe and had taken his degree at Edinburg. He had come especially under the influence of Cullen, whose views he had imbibed and later accepted in a modified form. He served two terms in Congress, where the duties of
of the times. The great benefit of the Revolution came from the presence of the educated and learned men, both at home and abroad, who came to the country and brought their books and wisdom with them.

The greatest figure in American surgery during the earlier part of the previous century was Philip Syng Physick. He was born in 1758 and died in 1837. He came of a good family and had a good education. But it was not until 1789, when, in London, he had the good fortune to be taken into the family of John Hunter, that he developed those qualities which helped to make him great in after life. Had he been willing to remain in the old country he might have become Hunter's partner. He had the best that the old country could afford, spending some 11 years in study, all told, which was a remarkably good preparation for practice 100 years ago. He yielded to the claims of his native land and quickly built up a practice after his return to this country. He had much with which to contend, including indigestion, an absolute lack of humor, in fact a temperament such as to make him unpopular, the only thing that saved him from his being his brains. In spite of all this he left behind him the reputation of being the Father of American Surgery. One of his most celebrated cases was that of Chief Justice Marshall, from whose bladder he removed an astonishing number of calculi. In 1805 he became professor of surgery in the University of Pennsylvania, which chair he held for 37 years. Though classy and uncouth in person he was singularly dexterous with his hands, and excelled in deftness with the knife, and with all forms of orthopedic apparatus. He gained great reputation in his treatment of fractures and dislocations, many modifications of which he made which proved very advantageous. For some years he had promise of a successor in his nephew, John Dorsey, who, however, died before his uncle, and never lived out his promised career.

The first prominent American surgeon was Ephraim McDowell, who came from what was then called the "Far West," in Kentucky. When young he went to a classical seminary, where he got a smattering of Greek and Latin, but not much else. He made his practice until he was 20. He began reading medicine in Danville, Ky., but was finally sent to Edinburgh by his father. Here he came under the influence of John Bell, whose teachings made him what he became. He returned in 1795 and decided that there was a rare opportunity in Kentucky for an educated physician, in which matter his foresight proved correct. In 1809, when he undertook the first and great historical 'Ovariotomy,' he was already known as an accomplished and educated man, upon whose mind the teachings of John Bell had made a great impression. When Mrs. Crawford came to him, suffering from an ovarian cyst, he was ready to undertake her case despite the protests of others. The case took 23 hours, with no gas and no ether. He bravely, and it was not until he had performed a number of similar operations that he thought it best to publish anything on the subject. Even then his paper did not see the light as it should, and then he died. It was a great thing, however, for those who should have known better as to whether his report was really authentic and whether he should be credited with this pathetic finding expedient. He has been amply vindicated, however, and this fortunate experience of his paved the way for many operations but for whose effects thousands of lives would have been sacrificed.

The next great figure was Valentine Mott. He was born in 1785, and was of Quaker parentage. He was a great classical student, and was well equipped for professional study when he began to study medicine. He then spent two years in Great Britain, especially in London, which was then rich in famous surgeons. Under Hunter, Cooper, Abernethy and Charles Bell he acquired that familiarity with surgical anatomy which was a great help both then and in later years. He returned to New York in 1809, and his personal traits as well as his thoroughness quickly brought him practice and made him known. He became the teacher of surgery in the Columbia School until he transferred his activities to the new school which resulted from the union of Columbia and the College of Physicians and Surgeons, where he lectured for 58 years. He was a man of constant enthusiasm and eagerness for work. The influence of his insistence upon the importance of anatomy still persists, and was brilliantly demonstrated by his work upon the blood vessels. It is said that he tied more large vessels than any other surgeon living or dead. Perhaps his greatest achievement, at least the one that made him most famous, was ligature of the innominate artery. This first operation of its kind was not permanently successful, nevertheless it stamped the operator as a man of wonderful resource and daring. The first successful case belongs to another American surgeon, A. W. Smythe, of New Orleans, who tied at the same time, the carotid artery in the neck. Again he won great repute by removing the entire clavicle for a large tumor. In 1827 he tied for the first time, successfully, the common iliac artery. The previous operation had been made by another brilliant American surgeon, Gibson, of Baltimore, whose patient unfortunately died of peritonitis. In 1835, quite broken in health, he made a tour of Europe, which had about it much of a triumph, insomuch as he was everywhere received with éclat.

We have also mentioned how, in 1778, John Warren served in the Revolution both as a surgeon and patriot. His son, John Collins Warren, was born in 1778, and was reared in an atmosphere of study and refinement. He was thoroughly educated for his work, in which he took the greatest pride, and, like Mott, had the advantage of the teachings and friendship of the most distinguished foreign surgeons. Two events of importance, in which he was conspicuous, were the founding of the Massachusetts General Hospital, and the introduction into surgery of the then new anesthetic, sulphuric ether, of which we shall have more to say below. He was a bold operator and for his operations on bones, especially the jaws, he became famous. He published the way for professional study of his personal cases in his "Surgical Observations on Tumors," which are to-day most instructive. He was the founder of the large collection of specimens now known as the Warren Museum, in Boston.

While Warren and Mott were making their great reputations in the East, it remained for Kentucky to produce still another even greater
than McDowell, in the person of Benjamin Winslow Dudley, born in 1785, who began life in an obscure way and who raised himself to eminence purely through his own attributes and strength of character. While quite young he made enough money, by a shrewd enterprise, to take him abroad where he remained several years, returning a polished and educated gentleman. Cooper and Aitkenhead in London, and Larrey in Paris, were men for whom he had much admiration and with whom he became well acquainted. When he returned he was 29 years of age, matured and devoted to his science. As a measure of his success it may be said that in his first 100 cases of cutting for stone in the bladder he lost not one; a statement that could be made by but few surgeons to-day. His early work in the surgical treatment of epilepsy directed attention to what could be done in this almost hopeless disease, and his treatment for hydrocele by excision of the sac is in common use to-day. For 20 years he was prominent in the Transylvania Medical School, in Lexington, Ky., which was largely managed by the College of Louisville. Dudley wrote very little, but his personal influence was extraordinary, and he was without doubt the leading practitioner of the West. He died in 1870.

In the interest of economy in space, it will be best, perhaps, to recount the various historical achievements of American surgeons without going into further biographical details. In the department of surgery of the large blood vessels the American surgeons were almost pioneers. In 1803 Cogswell of Hartford tied the common carotid, making the first successful ligation of this vessel on record. In 1807 it was first successfully tied for secondary hemorrhage by Twitchell of Keene, thus annulling Ashley Cooper's famous case by eight months. In 1813 Leet of New York first tied this artery for the cure of aneurism. In 1823 MacGill of Maryland first successfully tied both carotids simultaneously, the case being one of fungus tumor in both orbits. In 1867 Carneohan of New York first tied both carotids for the treatment of aneurism of the face and neck. Post, in 1817, first tied successfully the subclavian artery in its third portion, after it had failed in the hands of some of the great English surgeons. The same artery was first tied in its first portion by Rodgers of New York, an operation hitherto considered impossible, and which was never successfully repeated until 1892, by Halsted, of Baltimore. Mott's first ligation of three innominates artery has already been mentioned, an operation which made him famous all over the world. The internal iliac was first tied by Stevens in 1812, the external by Dorsey in 1811, and both internal and external by Dennis in 1866, while Davidge first tied the femoral and gluteal for the cure of elephantiasis of the lower extremity. Digital compression for the relief of aneurism was first successfully practised by Pemberton in 1848. The use of the elastic bandage in the treatment of varicose veins was first successfully adopted by Martin of Boston, who preceded Esthack in the use of this expedient for controlling blood supply during amputations; while Wyeth recently introduced long pins for the same purpose in amputation of the shoulder and hip.

In fractures and treatment of injuries and diseases of bones and joints, Physick exceeded all men, without question. The so-called American method, which is now so widely accepted, that is, the treatment of fractures by traction with a weight and pulley, was introduced by Daniel of Georgia. Van Ingen of Schenectady added to the method the elevation of the foot of the bed, and Buck increased its value by his application of splints. The present universal method is, therefore, a composite of all these, but is distinctly American. So is also the use of elastic traction by the aid of rubber bands. Barton, Bond, Hamilton and Reid, the latter of Rochester, all studied assiduously the mechanism of fractures and dislocations, and described the methods for their treatment and relief. The interdental splint for the treatment of fractured jaw was also of distinctly American origin. Rodgers introduced metallic sutures in the treatment of fractures; Brannam of Chicago, the method of drilling fragments in delayed union, while both Henry Smith of Philadelphia and Nathan Smith of New Haven did very much to improve apparatus for the retention of fragments in their proper places.

In the treatment of dislocations, especially in the matter of their reduction by manipulation, the world owes a great deal to Reid and Moore of Rochester, Bigelow of Boston and Gunn of Chicago, by whose efforts it was brought about that the ponderous machinery of the clinics was completely abandoned. In the removal of diseased bones Jamieson of Baltimore, in 1820, made the first resection of the upper jaw, while the upper and lower jaws were both simultaneously removed by Rodgers of New York. The first removal of the lower jaw was by Deaderick of Tennessee in 1810, while the clavicle was first successfully removed for necrosis by McCreary of Kentucky, in 1803, and for malignant disease by Mott in 1828, and the entire upper extremity, including the scapula and clavicle, by Crosby in 1836, and again the entire radius in the same year. Stone first removed a rib for drainage in 1852, and Mott the coccyx in 1832. Wood of New York had a famous case of enucleation of the lower jaw with almost complete reproduction of bone. Other operations of importance on bones were the first removal of a V-shaped piece of the hip, and also for the cure of bony ankylosis of the lower jaw. Nathan Smith of New Haven is entitled to the credit usually given Brodie for the trephining of inflamed bones for the relief of inflammation and abscesses.

In the matter of amputation Richard Bailey is to be credited with the first systematic amputation of the shoulder joint, in 1762. Crosby's case of the removal of the entire extremity has already been mentioned. The first successful amputation of the hip was made by Brash of Kentucky in 1806. The patient was a slave boy bought by the colonel of St. Joseph's College. The first operation of this kind ever done was in England by Kerr in 1774; while the first done for gunshot wound was by Larrey in 1793. American surgeons also made many improvements in gynecological surgery. The first successful plastic operation for extre-
Survey in America

The py of the bladder was made by Pancost of Philadelphia in 1858. He and others preceded Wood and various English surgeons to whom the credit is usually given. Parker of New York introduced cystotomy for the relief of chronic cystitis. The kidney was removed successfully by Wolcott and by Stoddard of Milwaukee nine years before it was removed by Simon of Heidelberg, who has been credited with it. The first really successful method of operation for cleft palate was introduced by J.C. Warren of Boston, while Cheever, another Boston surgeon, was the first to remove the tonsils by external incision.

In abdominal surgery Americans have almost led the world. Had it not been for McDowell's epoch-making case, in 1809, this branch of surgery would have been much retarded. Any one practising to-day can scarcely realize the moral courage and surgical daring required during that historical incident. Atlee of Philadelphia and Kimball of Lowell were the first to remove the bladder stones by cystotomy. It is claimed that Stevens of South Carolina, as early as 1763, successfully removed the entire uterus, an operation repeated by Briggs in 1830. The first vaginal operation for extra-uterine pregnancy was made by King of South Carolina in 1813, while the abdomen was first opened for this purpose by John Baird as early as 1759. Bobbs of Indianapolis was the first to attack the gall-bladder surgically, while Willard Parker first made clear the surgical treatment of peri-appendical, or as it was then called, perityphilitic abscess. The entire elucidation of the surgery and pathology of appendicitis is due to Americans, especially to Fitz and McBurney. The treatment of gunshot wounds of the abdomen by abdominal section was conceived, developed and perfected in America, especially by Bull and Parkes, while Sen, Murphy and others have made valuable contributions. The first four cases of pancreatic cyst were in the hands of American surgeons. The surgery of the female genital organs was close to the ingenuity and skill of Americans than to those of all other nationalities combined. Especially valuable in this direction were the labors of Sims and Emmet. Other procedures of modern surgery might be named without making the list too long; for instance, the invention of skin grafting by Dr. Frank Hamilton of Buffalo in 1854. The same procedure was independently instituted by Reverdin of Geneva, Switzerland, each being independent of the other. Animal ligatures were first used by Physick in 1844. The innocent character of the metallic ligature, as well as its usefulness, was first demonstrated by Levery, of Mobile. The use of plaster-of-paris splints and jackets was greatly promoted by Sayre of New York, although he was not their originator. The first abdominal section for gunshot wound of the intestines was made by Kinloch of Charleston in 1851. The discoveries and inventions of American orthopedic surgeons have been models for the rest of the world.

The two great events in the history of American surgery in the 19th century were the introduction of anesthesia and the antiseptic technique. Both stand to the credit of the American race, the former being an American invention, the latter a British device. These two measures together wrought a complete revolution in the practice of surgery, and show that the Anglo-Saxons have done more for it than had been accomplished in the previous 18 centuries. By the latter the devastations of sepsis have been almost completely done away with; and by the former the tortures of pain and the agonies of serious and protracted operations have been abolished.

Period of the Civil War.—The exigencies of the Civil War made demands upon the medical resources of the regular and volunteer armies which at first could not be adequately met; in this as well as other respects both sides were but meagrely equipped either with men or means. It was before the days of antisepctic surgery, bad methods still prevailed and the sacrifices then made to sepsis and to bad sanitation were fearful to contemplate. Wounds of large joints condemned the patient to amputation above the injury, compound fractures were very generally, fatal, hospital gangrene and tetanus were like aspera uterine fibroids, and it is claimed that Stevens of South Carolina, as early as 1763, successfully removed the entire uterus, an operation repeated by Briggs in 1830. The first vaginal operation for extra-uterine pregnancy was made by King of South Carolina in 1813, while the abdomen was first opened for this purpose by John Baird as early as 1759. Bobbs of Indianapolis was the first to attack the gall-bladder surgically, while Willard Parker first made clear the surgical treatment of peri-appendical, or as it was then called, perityphilitic abscess. The entire elucidation of the surgery and pathology of appendicitis is due to Americans, especially to Fitz and McBurney. The treatment of gunshot wounds of the abdomen by abdominal section was conceived, developed and perfected in America, especially by Bull and Parkes, while Sen, Murphy and others have made valuable contributions. The first four cases of pancreatic cyst were in the hands of American surgeons. The surgery of the female genital organs was close to the ingenuity and skill of Americans than to those of all other nationalities combined. Especially valuable in this direction were the labors of Sims and Emmet. Other procedures of modern surgery might be named without making the list too long; for instance, the invention of skin grafting by Dr. Frank Hamilton of Buffalo in 1854. The same procedure was independently instituted by Reverdin of Geneva, Switzerland, each being independent of the other. Animal ligatures were first used by Physick in 1844. The innocent character of the metallic ligature, as well as its usefulness, was first demonstrated by Levery, of Mobile. The use of plaster-of-paris splints and jackets was greatly promoted by Sayre of New York, although he was not their originator. The first abdominal section for gunshot wound of the intestines was made by Kinloch of Charleston in 1851. The discoveries and inventions of American orthopedic surgeons have been models for the rest of the world.

The two great events in the history of American surgery in the 19th century were the introduction of anesthesia and the antiseptic technique. Both stand to the credit of the American race, the former being an American invention, the latter a British device. These two
at that time were termed, abdominal surgeons. The outcome has been the organization of several national surgical associations, which have included in their fellowship some of the ablest of their breed, in the United States, thus enabling America to keep thoroughly abreast of all that was being done elsewhere. There has been a progressive development of bacteriological, biological and pathological laboratories where much research work has been accomplished, aiding very decidedly in the better understanding of surgical lesions, and resulting in a great increase in the possible operations to be performed for relief of the patient.

Hod the elder Gross, in his early experiments, in 1843, known of or had a laboratory at his disposal, such as exists to-day, greater honors would have come to him in doing intestinal surgery.

Laboratory work, with increased surgical skill, has brought about the establishment of many hospitals in the larger and smaller cities, and it may safely be asserted that in the latter many strong surgeons in the World War just brought to an end will be found doing superior work, the incentive will feel the good impulse of benevolence, excellent nursing and support from Red Cross organizations, while the larger hospitals in cities will become better endowed and less embarrassed in meeting their financial obligations.

It is very impressive to note how willingly communities have accepted going from their homes to the hospitals for treatment. Research work has brought out many surgical conditions associated with illnesses heretofore considered medical, such as lesions of the bones following typhoid fever, also tubercular conditions of the joints, syphilis, actinomycosis and other obscure lesions of internal organs, this advance being conducive to recoveries of cases formerly doomed to a long, painful sickness. Our laboratories have been of incalculable value in the preparation and standardization of absorbable ligatures; in the examination of the blood, and various secretions, and, especially, in the development of tetanus, antitoxin and other serums.

One great advance made by American surgeons has been the surgical treatment of the thyroid gland; another the energetic manner in which they have attacked the gall-bladder, the stomach, the intestinal tract, the spleen, pancreas and the reproductive organs within the pelvis, for conditions considered quite hopeless in the past. Operations upon the appendix, and intestinal tract, with the ability to remove portions of the latter, yet allow normal functions to follow in a healthy manner seem wonderful. This same confident development of surgical procedure has eliminated much of the distress due to lesions of the kidneys, the ureters, the bladder and prostate gland. All of this work could not have been accomplished without our knowledge of pathological microorganisms, and the employment of sterilization of the operating-room, the field of operation, the operator and dressings.

American surgeons had much to do with the prohibition of antisepsis, much has been accomplished. The battle has been to control suppuration,—i.e., the formation of pus,—and when every precaution has been carried out, when no link in the chain of infection has been omitted, to the public at large the recovery of patients becomes very noticeable.

In successful work surgery made a stride that commanded the respect and attention of wealthy citizens with a benevolent trend of thought, so that hospitals and laboratories were endowed, and in America we were able to do what for some time seemed only to be known in Europe.

Through the study of germs, in the various laboratories, and their danger to operative surgery, and with the employment of absorbable ligatures, the science and art of surgery has been brought up to a very high plane of activity. The advances made in operations upon the spine, and the treatment of curvatures from the long bones of the body, for the treatment of curvatures, has been one of the most decided advances in surgery. This is also to be observed in the immobilization of wounds, and in the fixation of fractures of the extremities.

Very much credit is due the American surgeon for discoveries and advances in local anesthesia in operative surgery, in hospital construction and for the persistent use of rubber gloves, particularly when operating in septic cases.

Some of the most brilliant advances made in surgery of the nerve trunks, in the removal of the Gasserian ganglia, for relief of neuralgia, had been accomplished by the American surgeon. The investigation, study and progress made in the department of genito-urinary surgery is one of the most convincing arguments that surgery has become more of a fixed science than ever in its past history.

The genius of the American surgeon is well shown, in so many ways, by the invention of new instruments, as well as the improvements made in those long in use, and in hospital furniture.

History of Anesthetics.—The abolition of pain is in itself a matter of such vast interest and humanitarian importance that a brief history of the introduction of anesthetics should be much appreciated, especially in a rehearsal of American achievements. Strictly speaking, the term anesthesia refers to the abolition of sensation of all kinds, whereas for the prevention of pain the term analgesia should be used. The distinction is an important one in certain cases; for instance in the injection of cocaine solution into the spinal canal, it produces the latter without the former, whereas by the use of the anesthetics now in use general anesthesia is produced. By general consent the term is restricted to complete loss of consciousness produced by such drugs as ether, chloroform and nitrous oxide, and not to the intoxication produced by drugs like opium, hashish or the mandragora of the old writers. The substance known as sulphuric ether had been known by the medieval alchemists in 1540, and was spoken of as sweet oil or vitriol oil. It was not called ether until 1730. In the earlier years of the previous century it was often inhaled for experiment or diversion because of its peculiar
exhilarant effects. Nitrous oxide gas had been previously used for the same purpose, and even for the production of anæsthesia. It will be seen, then, that these two anæsthetics had been well known for some of their properties. Chloroform, on the other hand, was not discovered until 1831, and was recommended as an anæsthetic until 1847. The honor of the introduction of ether into surgery is claimed for at least four men: Long, of Georgia; Jackson of Massachusetts, who were physicians; Wells, of Vermont, and Morton, of Massachusetts, who were both dentists. The first public demonstration of the value of ether as an anæsthetic agent, for the prevention of pain during surgical operations, was made 16 Oct. 1846 by Morton, at the Massachusetts General Hospital, before a group of men including some of those already mentioned in this article, especially Warren and Bigelow. In all probability Long anticipated this event by its use for a similar purpose in 1842, but in those days in this country the population was sparse, means of travel very slow and made public record of the event was ever made; in fact no account of Long's work appeared until 1849. To Wells probably belongs the credit of first producing anæsthesia by nitrous oxide gas, when he took it himself in 1844. After his own happy experience with it he began its manufacture and introduction to the profession. In 1845 Wells visited Boston, and even called on his old partner, Morton, endeavoring there to introduce his new compound for surgical purposes, but met with no encouragement. In Hartford there stands to-day a monument erected by the public, bearing the following inscription: Horace Wells, who discovered anæsthesia, November 1844. Morton had been a student in Wells' office, but not being a good chemist he consulted Jackson, whose office he later entered, and by whom he was advised to experiment with ether. Jackson told him, for instance, that the students at Cambridge often inhaled it for amusement, and in 1846 he first gave it for the extraction of a tooth, the patient thinking that he felt no pain. Then came efforts to patent the new anæsthetic which were not to the credit of either Jackson or Morton. Finally came the public demonstration above alluded to, when Morton administered his ether, which Wells removed without pain a tumor from the neck of a young man. At this time Morton endeavored to disguise the odor of the substance he was using so as to prevent its recognition, and it was not until the hospital staff declined to use any substance whose composition was kept secret that Morton revealed his discovery. During the ensuing years there took place a most active and acrid controversy between the partisans of the men most concerned in the introduction of ether into surgical work, as to the respective merits of their various champions. A dispassionate judgment of the whole indicates that to Wells, doubtless, the credit of the introduction of nitrous oxide belongs. Long probably was the first to use ether in a surgical way, but was slow in pushing the use of his discovery. Morton finally became the promoter of the new agent, partly by virtue of his own energy and partly because of his acquaintances and surroundings. Chloroform, although discovered independently by Guthrie, of Sacketts Harbor, N. Y., in 1831, was introduced into surgical work by Simpson, of Edinburgh, who advised it especially for the relief of the pangs of childbirth, and who was, in consequence, violently assailed by the Scottish clergy as interfering with the spirit of the primal curse which read: *In sorrow shall thou bring forth children.* Simpson, however, disarmed his opponents by a quotation, also from the Scriptures, to the effect that when God created Eve from one of Adam's ribs, he *caused a deep sleep to fall upon Adam.* It will hence be seen that, at the date of this writing, it is almost 70 years since it became possible to make surgical operations painlessly. What this means both for the surgeon and the patient will be appreciated, while what it has made possible can be easily realized by contrasting the resources of the surgeon of to-day with those of the middle of the 19th century. See Visitation — Its Influence on Surgery.

ROSEWELL PARK,
Author of 'Text Book of Surgery,'
ALBERT VAN DER VEER,
Professor of Surgery, Albany Medical College,
1878-1915.

Surgical Association, American, a society organized in 1880, the objects of which are to promote the improvement of the science and art of surgery. The active membership is limited to 125 Fellows and the honorary membership to 25 Fellows. An applicant for Fellowship must be 30 years of age, a graduate of five years' standing from a recognized medical college and have an established reputation as practitioner, author or investigator. Meetings are held annually and an annual volume of Transactions is published. Every third year the association joins with other associations constituting the Congress of American Physicians and Surgeons in a meeting held in Washington, D. C.

Suricate, or Meerkat, a South African civet (Suricata tridactyla), which differs from typical viverrines in several points, notably in having only four toes on each foot. It is dark brown and has dark transverse stripes on the rear of its back. The body and head reach a length of 12 or 13 inches, the tail 6 inches and the animal has a general resemblance to a small raccoon, but the tail is more cat-like. It lives in caves and rock-cavens or sometimes digs burrows. It is diurnal, lives mainly on roots and barks like a dog. Consult Martin, 'Home Life on an Ostrich Farm' (New York 1903).

Surigao, soo'o-ré-ga'oo, Philippines, (1) Town, capital of the province of Surigao, Mindanao, on the extreme north coast of the island of Mindanao. This district was the site of the first Spanish mission in the Philippines; in 1579 a series of earthquakes caused the ground in the neighborhood of the town to sink two feet and many of the government buildings were rendered uninhabitable for a time. The chief industries are the gathering and export of pearl shells and tarpag and the placer mining of gold. Pop. 7,749.

(2) Province, island of Mindanao, occupying the northeastern part of the island; area, 6,988 square miles. The principal dependent island is Dinagat, lying off the north coast;
it is mountainous, heavily wooded and has deposits of gold; area, 387 square miles; the second island in importance is Siargao (q.v.), 190 square miles. The province is traversed by two mountain ranges, extending from north to south, one near the east coast, the other forming the western boundary; spurs of these ranges extend in both directions. The central valley is drained by the Agusan River, entering the Pacific Ocean in the Philippines. Cotton, hemp, rice, sugar, tobacco, indigo, etc., are cultivated; the coconut, betel nut and betel pepper are grown for export. Gold is found in the mountains and in the sands of the mountain streams and is mined; the forests are valuable, and gums and resins are obtained in large quantities; fishing is an important industry, and there is some weaving of native fabrics for home use. There are few roads, the communication is by sea or by the rivers and lakes of the central valley. Civil government was established in the province in May 1901, but the jurisdiction of the provincial government does not extend to the non-Christian tribes. Pop. 11,551.

SURIGAO. Strait of, connecting the Sulphur Sea with the Pacific, having Mindanao on the south and the islands of Leyte, Panaon, Bohol, Cebu, Negros and Samar on the north. It was the route taken by Magellan after crossing the Pacific. The San Bernardino Strait is now used more than Surigao during certain seasons, but Surigao is the more direct, deeper thoroughfare and the more advantageous route for vessels bound for the southern Philippines.

SURINAM, soo-rë-nëm'. See Guiana.

SURINAM TOAD, or PIPA TOAD, a toad of the South American family Pipidae; specifically Pipsa americana. It is one of the largest and the most repulsive-looking of the toads and is noted for its extraordinary mode of developing the eggs and young: When the female is about to expel her eggs the male mounts upon her back and the eggs as they are extruded are squeezed upward between the back of the female and the belly of the male, while they stick to her skin and gradually sink into the spongy skin, each occupying a pit with a lid. Fertilization takes place by some process not well understood just before the extrusion of the ova. The eggs remain in the pits until they have reached a mature condition (although, yet very small) and then escape into the water. Consult Gadow, 'Amphibia and Reptiles' (New York 1901).

SURMULLET. See Mullet.

SURNAMES. A surname is a name added to a baptismal or Christian name which makes it more specific, and is generally a family designation. It may be indicative of descent, habitat, occupation, craft, or may have originated in totemistic associations, clanship, personal peculiarities or from vulgar nicknames. A proper name, once given or adopted, becomes in time a part of the individuality. The giving of names is not necessarily proof of an advanced civilized condition. It may be considered coeval with and intimately connected with the gift of speech; the Adamic tradition of the origin of common names is a sate than presupposed to preclude Adamic savagery. The primal family grew into the primal tribe, and proper names became necessary; the land and the gathering of men upon it necessitated proper designations for each, or the same name for both.

All proper the grandparent, at first, a peculiarly appropriate meaning, which in time often becomes obscured and ultimately forgotten. Schlegel traced descriptive epithets in almost all Hindu names, and the older names among the Hebrews, Arabs, in fact all Oriental nations, are highly significant and personal as "son of wool," "son of wealth," "son of the scythe," "young of dog," "prince of the dogs" among the Tcherkessians of Mount Caucasus. This is measurable true of names of Aryan origin, and noticeably those of Teutonic and Scandinavian lines. The North American native is usually named from some animal, for totemic reasons, and later earns another from some deed of daring performed; and similar practices prevail in all savage tribes. In fact, the origin of heraldry may be looked for in totemic devices and symbols.

The study of proper names is useful in historical and literary researches—as important as numismatics, heraldry, superstition, symbolism and tradition. The name of a man often retains the impress of his country, and sometimes of the period in which he lived, and may thus furnish a clue to correct a date or vague notion, or to settle a disputed question in chronology, geography or genealogy; the conquerors of Andalusia, the Vandals, gave their name to that province, and it is hence not derived from Andalus, son of Japhet and grandson of Noah; the posterity of one man cannot, in reason, cover 30 degrees of longitude, in three generations, in a barbaric age.

In Rome, family or clan names were hereditary, but surnames remained individual, sanctioned by public consent, as Scipio Nasica, Piso Frugi, Lentulus Sura. In the republics of Greece, notably Athens and Sparta, men's names were significant of the power, valor, virtues or victories of the people, as Agesilaus, Charidemus, Demagorus, Demophilus, Demosthenes, Laodiece. In fact it is common among all peoples to exaggerate the importance of the significance of names. Both Greeks and Romans augured well or ill from them. Grecian names are significant, either of religious feeling, the remembrance of great events, some happy omen, chance, friendship or gratitude. Daughters were named from their fathers more scrupulously than were the sons; Homer uses their names in this wise without exception, as Chryseis, the daughter of Chryses; Briseis, the daughter of Briseus. The son's name was frequently an enlarged form of the father's, as it was deemed that polysyllabic names were more honorable than shorter ones, which were given to slaves: the Spartan Hegesander named his son Hesander, tyrant of Syracuse, named his son Hieronymus. There are traces of a desire to adopt family names, among the Greeks, but it generally ended in a vague reference to the hero from whom the family sprung; these are names which were only adopted by those families who pretended to trace back to deities or fabulous periods of history.

The Scandinavians and largely the Germans had none but individual names; every family, as with the Greeks, showed a decided preference for certain names, and these were generally transmitted from grandfather to grandson,
or from uncle to nephew, for some occult reason, while the daughter was only known by her father's name (as All-hide meaning literally the child of All's). Others retained the root from which the head of the family derived his name, but varying the syllable of this; the three sons of the formidable Argrim retained the last syllable which signified rage). There were thus no family names among the Celts, strictly speaking. The songs of the Druids have perished, with the names of the heroes that sang of; but more fortunate were the heroes of Erin and Morven, for the ancient national songs still exist in Ireland and Scotland.

The need of surnames began to be felt. Many would naturally prove themselves "dreadful-in-the-fight," "Hardy," "Stern-of-look," and the Northern nations soon adopted a method of adding the father's name to the son's; as Oscar son of Ossian, Oscar son of Caruth, Dermid son of Dutho, Dermid son of Diaran. The introduction of Christianity, which taught the equality of man, breaking up class distinctions, rapidly advanced the adoption of surnames by the use of new or baptismal names — Biblical or saints' names, anything but pagan cognomina, much caused trouble; the new names were almost wholly derived from foreign languages, and as such had no local or personal significance.

The rise of feudal power was another source of change and confusion, as retainers or feepees often bore the name of their overlord, whose title might arise from his office at court or his most valuable estate. The division of estates led to a new distribution of surnames among the heirs, taken from the inherited estates, only the oldest retaining the father's name by reason of the name being attached to the home-estate. The charters of the 10th and 11th centuries often recited the same individual under different names — sometimes because he had lost the manor which gave him title, or had come into possession of another which was more flattering to his vanity. The law of primogeniture finally cleared away much confusion, the property becoming settled in tenure and the owner dealing with his paternal property; from that time a surname was rarely lost and was further confirmed by the granting of armorial bearings.

In heraldry we find many surnames derived from "canting arms," which clearly proceeded from the arms; as in Sweden, the family whose arms represented the head of an ox took the name Oxenstierm (like the well-known Front-de-Boeuf); the Racines had originally placed in their coat-of-arms a rat and a swan (Nat-Gyne), but the writer of "Athletic" retained only the swan, as the rat offended his taste.

To England the Saxons brought their feudal institutions; immense properties were attached to the land, and the Thanes, and then formed out to substantial tenants who again let them to subtenants for cultivation. William the Conqueror redistributed these lands as fiefs among his Norman warriors; Henry I, a 1100 changed the fief tenure into real or frehold property, but his concession produced to great increase of hereditary names. In 1160 Henry II enfranchised the land in order to counteract the ambitious barons; soon after his time hereditary names became common in England.

It appears that surnames began to be adopted in England about 1000 A.D., coming mainly from Normandy. A few Saxons had surnames: "Hwita Haite was a keeper of bees in Northfelda, and Tate Haite, his daughter, was the mother of Wulfige, the squire. In the Cottonian manuscript shows a transition point. In the time of Edward the Confessor there were Saxon tenants in Suffolk: Leuristic Hobbesone (Hobson), Suert Magno or Manni, Godric Point, Suert Robert of Red Ruth (redhead) and Stigand Soror. In the Domesday Survey they were becoming more common: as Alwin Dodesone (Dodon), Walter Achet, Osmund Anglevin, Roger Arundel, Walter Bc, William Bonvaslet; some of these being curious Norman blends of their own names with those of their Norman masters, as above in Arundel and Anglevin. When King Magnus assumed Highland dress he became known as Berbein (Breveleg), still preserved, probably, in the Puritan "Barebones."

The terminations "ing, kin, son, in English names, were derived from the Norse "ingr, kyn and sonr, the being dropped. The Danish make the last sen. The diminutives: Friesian, "etten, ke, ock, eck (a lasting folk), Scotch "gowkies"; Norman-French et, ette, let, ot, otte, et; Old Norse, i, a, ki, go, ga, ungr, ingr and lind, became quite common additions to English names, which have since adhered.

The Gaelic Mac, Irish O, the British Ap, the Norse ungar, the Friesian ingar and en, the Anglo-Saxon ingr, the Norman Fitz (probably from Flanders originally; many Irish families substituted Fitz for Mac in Norman times) are all ancient family prefixes. The ancient tribe of Waring or Wearing, the Veringi or Veringun (originally from the Veringiford in Norway) formed the celebrated Varangian guard of the Byzantine emperors, which was afterward largely recruited from the North and especially from England.

In England, as of old in Schleswig, the village community formed the unit of English society. Each such township was still bounded by its mark of forest, mere or fen, which divided it from his nearest neighbors and lived a single clan, supposed to of kindred blood and bearing a common name. Many family names are thus perpetuated in England; as the Bassingas at Bassingbourne in Cambridgeshire; at Basingfield in Notts; at Basingthorpe and Basingham in Lincolnshire; and at Basingham in Northumberland. The Billings have left their stamp at Billing in Northampton; Billingford, in Norfolk; Billingham in Durham; Billingley, in Yorkshire; and Billinghamurst, in Sussex, Birmingham, Nottingham, Wellington, Parington, Warrington and Wallingford are well-known names formed on the same analogy. In London alone occur the old Saxon settlements at Kentington, Paddington, Notting-hill, Billingsgate, Islington, Newington, Kennington, Wandsworth, and Bethnal. There are altogether 1,400 names of this type in England.

Totemism consists in the belief that each family is literally descended from a particular animal or plant whose name it bears and members of the family formerly refused to pluck the plant or kill the animal after which they were named. The genealogies of the Anglo-Saxon kings include such names as those of
the horse, the mare, the ash, the whale. In the ancient poem 'Beowulf,' two of the characters bear the names of Wulf and Eoefer (boar); the wolf and the raven were sacred animals. The names on the Christmas boar's head is a survival of the old belief. The oak has left its traces in Oakington, in Cambridge; the birch, at Birchington, in Kent; the boar (eoefer) in Ervingham in Yorkshire; and the horse at Hornington, in Lincolnshire; the raven, at Ravingham, in Norfolk; the sun, at Sunning in Berks; and the serpent (wyrm) at Wormingford, Worminghall and Wormington in Essex, Bucks and Gloucestershire, respectively. Every one of these objects is a common and well-known totem among savage tribes and the inference that at some early period the Anglo-Saxons had been totemists is almost irrefutable.

The suffix *atte*, as implying residence, if not possession, crept in, and thereby arose such names as Atte Bourne, Atte Brigg, Atte Hash, Atte Hay, Atte Kirkstile, Atte Lane, Atte Maydens, Atte Sile, Atte Well; the modern names of Atwood and Atwell occur to us today. The *de* and *atte* were often dropped, hence arose names like Wood, Lane, Briggs. Many names that seem to defy all explanation are disguised beyond recognition; as, who would expect to find Sevenoaks in Snooks; Saint Olave's street in Tooley Street; Saint Etheldreda in Tawdry; Douglas in Diggles; Wilburgham in Wilbraham; Tuberville in Troublemfield; Longueville in Longfellow; Longchamps in Longshanks; Blondewell in Blundell's field; Adburgham in Abraham and Abram; Renshaw in Wrencher and Wrinch; Wymondham in Wyndham. As Mr. Lower truly says: 'Corruptions which many family names have undergone tend to baffle alike the genealogical and etymological inquirer.'

The name of Shakespeare has had at least 27 permutations in old documents; Goodwin, 17; Finnmire or Philimire 59 and 34 of the latter surname.

When the country became settled under Edward the Confessor and the Norseman, Saxon and Welshman lived together under a semblance of law and order, official names arose as Laggman (lawgiver), Fawcett (forseti, judge), Alderman, Shrift, Tabberne, Chamberlain, Chancellor, Chaplain, Clerk, Deacon, Beadle, Latimer (Latinarius, an interpreter), Miles (miles, a soldier), Marshall, Sumner (a summoner, as Chaucer's 'Somnpoure'), Parker (a park-keeper), Franklin (a freeholder), Boiler (butter). Trade names and craft names are of later origin; but it is an open question whether some of the names popularly ascribed to occupations will not bear different interpretation.

Because America is a country made up of all races, it is obvious in the United States a greater variety of names than anywhere else on the globe. Russian, Polish and middle European names seem particularly hard for the American to grasp, and, therefore, immigrants, finding their long names a handicap, are apt to shorten them slightly, reverenced and cons, and Rawitzer is shortened to Rawser. There is also a tendency to translate names. Herr Vogel becomes Mr. Bird, and Mons. Pantofflen is Mr. Slipper. One is amazed at the combinations disclosed in any large directory, as in the firms of Au and Magenheimer, Stretch and Shrink, and the famous Call and Tuttle, Preserved Hookins, Singular Orions Gallyhawk and Esa Hogg must each and all bear grudges against those who infiltrated such names on the commonwealth. But all of these names have appeared in city directories.

**SURPLACE**, a garment of white linen, sometimes adorned with lace, worn over the cassock by priests, choristers and other attendants in the chancel during the service and by ministers in the solemn administration of the sacraments. It is usually a loose, flowing garment, varying in length: in the 12th century it reached to the ankles and this length was prescribed by the Council of Basel (12th century); in the Anglican Church the surplice reaches almost to the feet. In the Roman Catholic Church its length is much less, never extending below the knees, while in the Italian fashion it does not reach nearly so far and is known as the cotta. See Costume, Ecclesiastical.

**SURRA**, a disease of domestic cattle in the Philippines, due to the presence in the system of a protozoan parasite.

**SURRENDER**, in law, the restoring or giving up, as an estate for years, to the reversioner or remainderman, by which act the surrendered estate is merged in the other; also, the written instrument evidencing such surrender. It should be distinguished from a release, which is an alienation of the estate by the reversioner or remainderman to the tenant. It should also be distinguished from a renunciation, which is the refusal to take an estate to which one is entitled by law. A surrender by agreement must be in writing, but it may take place by act of the landlord accepts another person as tenant.

**SURREY**, sur'li, Henry Howard, English poet: b. about 1517; d. 21 Jan. 1547. He was the grandson of the Earl of Surrey who was the victor at Flodden, and who, as a reward for his services, was created Duke of Norfolk. He succeeded to the courtesy title of Earl of Surrey when his father became third Duke of Norfolk of the Howard house in 1524. Surrey became companion to the Duke of Richmond, a natural son of Henry VIII, and in 1533 travelled with him to the French court. He took part in the suppression of the Pilgrimage of Grace in 1536 and in the following year was imprisoned for striking a courtier who had repeated a rumor of his sympathy with the rebels. He served in the army on the Continent and in 1545 was appointed commander of Boulogne, but he was shortly afterward defeated by the French and superseded in his command. Shortly before Henry's death Surrey and his friend Tolins was arrested at the throne and were arrested and lodged in the Tower and Surrey was tried, condemned and executed. In 1538 there was published his translation of the second and fourth books of Virgil's 'Ennius,' the first attempt at blank verse in English. He also wrote many sonnets
after the Italian model. There is an edition of his works in the 'Arber Reprints.' Consult Hales, J. W., 'Folia Literaria' (London 1893).

SURREY, a kind of light carriage having two seats in a box mounted on side bars, four wheels and sometimes a top.

SURROGATES, formerly a deputy, a substitute, a delegate, a person appointed to act for another. In the United States, an officer who presides over the probate of wills and testaments and the settlement of estates. In English law, one appointed by a bishop or his chancellor or by an ecclesiastical judge, to issue licenses for marriages without banns and to deal with probate and kindred matters.

SURROGATES' COURTS. See Court.

SURTEES, ser'tez, Robert, English author: b. Durham, 1 April 1779; d. 11 Feb. 1834. He was graduated from Oxford in 1803 and studied law at the Middle Temple till he inherited his father's fortune. He was elected to the House of Commons for Stockton in 1817, and in 1826 for the Bishopric of Auckland in New Zealand. Henceforth he devoted himself to preparing a 'History and Antiquities of the County Palatine of Durham' (1816-23), to the fourth volume (1840) of which, completed by Raine, a 'History of Surtees Society,' was prefixed. The Surtees Society, founded in 1834 for editing unpublished manuscripts chiefly relating to the northern counties of England, published its 73d volume in 1894. Consult Taylor, G., 'Life of Surtees' (Durham 1852).

SURVEYING, the science of determining accurately the relative locations of points and lines on the earth's surface and of recording the same on maps; it includes also the reverse operation of discovering and locating on the ground points and lines depicted on a surveyor's map.

Two principal kinds of surveying are recognized, plane and geodetic. In plane surveying the area which is the subject of survey is regarded as a plane surface, the curvature of the earth being disregarded. In geodetic surveying, which deals with areas of large extent, the curvature of the earth is considered and given its proper circumstance.

Plane surveying consists essentially of the linear measurement of lines and the special measurement of angles, either vertical or horizontal; together with the subsequent calculation of the content of areas to which such lines and angles appertain. It includes as classes (1) land surveys — the defining of the boundaries of land areas; (2) topographical surveys — the determining of variations in altitude and the denotation of physical characteristics; as, for instance, roads, rivers, forests, swamps, etc.; (3) construction surveys — the staking out of boundaries of railways, etc.

As the earliest records of man refer to skillful measurements and calculations, it is impossible to assign the birth of the science of surveying to any particular year or even century. Foreign states that, according to the Chaldæans, 4,000 camel steps make one mile, 66 2/3 miles one degree, from which the circumference of the earth is 24,000 miles. A papyrus in the British Museum, written 1700 B.C., gives rules for calculating the areas of triangles, trapezoids and circles and the works of Heron of Alexandria (285 B.C.) mention mine surveying and the relatively crude instruments used at that time.

In 1617 Snellius, in Holland, made one of the first attempts to determine accurately the earth's radius. Picard, in 1667, adapted cross-wires to a telescope. In 1735 the French Academy of Sciences sent out two surveying expeditions, one to Peru and one to Lapland. The latter resulted in the first demonstration that the earth is not a sphere but an oblate spheroid. The invention of the vernier by Vennerus in 1631 and of the transit by Roemer in 1672 gave an impetus to the science of surveying, the final results of which are yet to be achieved.

Chain Surveying. — A great variety of work can be done by the use of a chain or tape alone, as, with the measuring of straight lines, the areas of triangles, rectangles and even polygons can be ascertained by dividing the polygon into triangles which are then measured. Angles can be ascertained by laying off equal lengths, b, from the vertex, A, on the two lines, then measuring the third side, a (base of isosceles), and using either of the following formulæ:

\[ \tan \frac{A}{2} = \frac{a}{2b} \quad \text{or} \quad A = \frac{2 \tan^{-1} \frac{a}{2b}}{2b} \]

The angle may then be looked up in a table of sines and tangents. The measurement of inaccessible lines can also be accomplished with the use of only an accurate tape line, as shown in the accompanying Fig. 1. Assume CB to represent the distance to be laid out from C a perpendicular line (CD) to the point D, from which also the point B is visible; and from D lay DC off DC perpendicular to DB, cutting the extension of the line BC at E. There are then the two similar triangles whose corresponding sides are proportional; and we have the proportion—

\[ DC : CB = CE : DC \]

and from which we find

\[ CE = \frac{DC^2}{DC + CB} \]

It remains only to measure DC and CE with the closest accuracy possible and to substitute their values in the proportion. The laying off of the perpendicular to the point B is made by the use of the pons asinorum of the geometry — the square of the hypotenuse of a right-angled triangle is equal to the sum of the squares on the other two sides. In surveying practice this becomes the striking off of two conical points X and Y respectively, these two points being eight feet apart. The radius of the curve from X is to be six feet, and that from Y 10 feet. The point Z where these curves intersect will be in a perpendicular to XY from the point X, the angle XYZ being a right angle. But such measurements are not comparable with work done with the aid of the transit.

Compass Surveying. — The use of the azimuth compass is considerably restricted for several reasons, namely: The magnetic needle points north at but few places on the earth, the disagreement varying from 1° to 30° from true north. This disagreement, or the angle between true north and the magnetic needle, is called the declination of the needle. The declination does not remain constant, however, there being diurnal, annual and local variations from the normal declination which introduce unknown errors in the compass survey. The diurnal variation is usually not more than 6 minutes but may reach 20 minutes. It is usually zero at 11 o'clock A.M.; the annual,
1 to 2 minutes, and the local variation amounts to as much as several degrees in some localities, owing to deposits of iron ore near the surface. Errors from this source may be avoided by back sights at each station. There are also secular variations in the declination, so that when retracing the lines of a compass survey made several years previously, the surveyor must use the same declination used in the original survey. In making a compass survey it is necessary to determine the declination of the needle by an observation on a polar star, or on the sun with the aid of a solar attachment (see below). The stellar observation is usually made on Polaris which, however, is not precisely at the north pole. It is necessary, therefore, to make the observation exactly at the time of upper or lower culmination, or at eastern or western elongation; a correction being required in the later case. Tables have been published, however, by the United States Land Office for taking the observations on Polaris at any convenient time.

Government Land Surveying.—The first public surveys in the United States were made in the State of Ohio under an ordinance of the Continental Congress passed 20 May 1785. This ordinance was slightly modified by an act of Congress, passed 18 May 1796. This act, which is still in force, provided that all public land, except certain private land grants, shall be divided into townships six miles square, and that sections shall be subdivided into one-fourth sections one-half mile square. The act further provides that all lines of public land surveys shall be run on either true meridians or true parallels of latitude. The method of surveying townships and sections is as follows: First — In each State, or convenient group of States, there is established a principle (true) meridian, and, at right angles thereto, a base line conforming to a true parallel of latitude. Second — Standard parallels or correction lines, also conforming to parallels of latitude, are established at intervals of 24 miles north and south of the base line. Third — Guide meridians conforming to true meridians are initiated at intervals of 24 miles along all standard parallels, and run due north to the intersection of the next standard parallel. Fourth — The rectangles thus formed by the guide meridians and standard parallels are subdivided into 16 townships. As meridians converge toward the north pole the north boundary lines of townships are less than six miles long and offsets required at any latitude in the United States.

Traversing.—This is a method of surveying a polygon by surveying its perimeter only, as distinguished from the method of cutting the polygon up into triangles (Fig. 5). In a traverse survey the transit is usually oriented at each station, thus referring all bearings to a magnetic meridian. In mapping such surveys the "north point" shows the magnetic north at the date of the survey and a skeleton arrow is drawn through it showing the needle's declination at that time and place from true north. It
is not necessary to take convergence of the meridians into account except in geodetic work. The method of procedure is as follows: The transit is set up at station No. 1 and the bearing and distance of the first course determined. The transit is then removed to station No. 2. With vernier 
\( \Delta /x \) still at the previous reading, the lower spindle is unclamped and a plumbed rod bisected at station No. 1, with the telescope inverted. The telescope is then revolved to its normal position, unclamped, and the bearing and distance to station No. 3 ascertained. The transit is then removed to station No. 3 and the operations repeated. To illustrate this important branch of surveying the tabling of a traverse and the rules governing the same are given in the table on the preceding page.

In the foregoing "tabling" the latitude and departure of each course is found by multiplying the distance by the cosine and sine of the angle expressed by the bearing. The latitude and departure ordinates are self-explanatory.

The single meridian distances are the departures of the respective stations from the most westerly station. The double meridian distances of the respective courses are equal to the sum of the single meridian distances of the stations at each end of the respective courses. Each North and South area is equal to the product of the latitude of a course into its corresponding double meridian distance. The area of any polygon is equal to one-half the difference between the sum of the North and South areas. When the course and distance of any side of any polygon is lacking it is found as follows: Ascertain the difference between the north and south latitudes and the difference between the east and west departures. Divide the difference in departures by the difference in latitudes for the tangent of the bearing. Divide the difference in departures by the sine of the bearing found, for the distance.

Topographical Surveying.—In order to facilitate the selection of a route for a railroad, to properly locate an irrigation reservoir or dam for power purposes, or to correctly make a geological survey of a large area it is generally necessary to make a topographical survey of the area under consideration. From the field notes of the survey a map is made showing the surface elevations with considerable particularity by a system of contour lines at stated differences in level, and also showing all important objects, such as buildings, roads, canals, fences, streams, etc. There are several methods of making a topographical survey. First, by the use of a tape, level and transit. Second, by the use of the plane-table. Third, by the use of a transit and stadia rod. The last-named method alone will be discussed here, it being the method usually adopted, on account of its celerity and low cost. Stadia wires are two horizontal wires placed in an adjustable ring so that they appear at equal distances above and below the horizontal cross-wire when looking through the telescope.

The theory of stadia measurements is based on the two following equations:

\[
\begin{align*}
1. & \quad \frac{1 + \frac{1}{f_1}}{f_1} + \frac{1}{f_2} = \frac{1}{f} \\
2. & \quad \frac{1}{f_1} - \frac{1}{f_2} = \frac{1}{f} 
\end{align*}
\]

in which \( f_1 \) is the height of image or distance between the stadia wires, \( c \) the height of object or the stadia reading on the rod, \( f_2 \) the

![Diagram](image-url)

**FIG. 4.—Land Surveying Secant Method.**

...
In topographical field work where the area to be surveyed is considerable it is usual to first lay out a triangulation net work, all measurements being made with a tape or by triangulation from an accurately measured base line and the stadia measurements taken from the triangulation stations. In work of less magnitude it is not necessary to lay out a system of triangles, but all measurements from station to station are carefully made and checked by cross-readings. The location of objects is quickly and accurately accomplished by sights from two different points of the measured line. In making a map of a topographical survey there are several methods employed. One requires the use of a T-square and brass protractor, another and a better method is by the use of a protractor sheet larger than the sheet upon which the drawing is to be made. After all distances are laid off and the heights indicated at the various points, contour lines are drawn in by proportioning the distances and heights; or reference to heights. Sometimes the contour lines are drawn in pencil to be afterward erased and the hatchure method of representing topography employed.

Mine Surveying.—The chief purposes of an underground survey are to ascertain the amount of ore in sight, to find the pitch and position of the "pay chute" with respect to the shaft and levels, to find the "dip" of the vein and also to ascertain and lay out the direction of connections commonly called "hollings." Moreover the laws of some States and countries require plans of the underground workings to be kept on file. Ventilation being one of the serious problems in mining—especially coal mining—it is generally necessary to make passageways or "hollings" connecting the various drifts and levels in such a way as to facilitate the circulation of fresh air throughout the mine. In order to make these connections a careful transit survey is necessary, the compass needle being unreliable in the presence of pipes, rails, ore cars, etc. While mine surveying does not call for the precision of a geodetic survey, cases arise requiring great skill and ingenuity. One of the chief difficulties is to transfer the bearings and azimuths to mine line to work later. This is especially difficult if the survey has to be carried down a deep vertical or inclined shaft. In vertical shafts heavy plumb-obs suspended in pails of water or molasses at the bottom of the shaft by means of wires reaching to the surface have been successfully used. A transit with a secondary telescope, so attached to the extended axis of the primary telescope that it may be sighted vertically downward, is also used for this purpose. In underground work it is necessary to mark points out and internal to the mine to make tape measurements on the slope or level as the circumstances may permit. Illuminated plumb-lines are used for fore and back sights and it is also necessary to hold a candle so as to illuminate the telescope cross-wires. Permanent pegs for future use are usually placed in the roof instead of in the floor of a drift and even then their position must be often checked for ground moves considerably in some mines.

Geodesy.—This branch of surveying has for its object the exact location of points and lines with reference to the true form of the earth. In most geodetic work the earth is assumed to be an oblate spheroid, all measured angles and distances being reduced to spheroidal angles and distances. The United States Coast and Geodetic Survey has adopted the Clarke's spheroid of 1866. The foundation of a geodetic survey is a base line. This is most carefully measured with specially constructed bars of invar steel (q.v) encased in wood, called a "Base line apparatus." Base lines can be measured with steel tapes with an accuracy of one in 1,000,000 under favorable circumstances. These tapes have a screw adjustment for temperature as shown by a thermometer in the handle and there is also a helical spring attachment for regulating exactly the pull used in stretching the tape. Two tapes are used in each measurement and, in case of disagreement, are compared with a third and fourth tape. An accuracy of one in 300,000 is generally accepted as satisfactory. With a base line as a nucleus, a system of triangulation is put over the surrounding country, additional base lines being measured from time to time to serve as a check upon the work. In a primary triangulation the sides of the triangles are very long—20 to 100 miles. The first series of triangles laid from the base line are as nearly equilateral as can be made. This conduces to accuracy in the larger triangles. Within the primary triangles secondary and tertiary triangles are laid out, the lines of which are from 1 to 20 miles in length. Angles are measured with specially constructed transits, average results of several readings by the "continuous reading" method being necessary. The unknown sides and angles of the spheroidal triangles are calculated and, when possible, the angles are checked by actual observation. Vertical angles are also read at each station and corrected for refraction and curvature of the earth. The permissible error in a primary triangulation by the United States Coast and Geodetic Survey is one-fourth inch per mile or one in about 250,000; the permissible error in the measurement of an angle is three-tenths of a second and the closing error must not exceed five seconds, or one in about 250,000. As it is impossible to attain such accuracy it is necessary to adjust the angular measurements by a system of averaging errors. In determining the azimuth of any geodetic line the convergence of the meridians has also to be taken into account.

Hydrographic Surveying.—This includes surveys for determining the depths of water in rivers, bays and harbors for purposes of navigation; the determination of velocity and direction of currents; the location of hidden rocks or shoals and buoys, lights, etc.; and the determination and measurement of all soundings carried by streams and deposited in bays. Permanent bench-marks and stations are generally made on shore, and the points at which soundings are taken located by triangulation. There are several methods of locating sounding points. First, an observer is stationed at each end of a base line. At the instant the man on the water makes a sounding he signals the two transmitters to take their observations for azimuth. Second, by the "three point problem." That is, by reading from the
SURVEYING

boat two angles to three points on shore whose relative distances are known. Of course, sextants only can be used for measuring angles from the boat.

Soundings are taken in feet or fathoms, the mean water level being taken as the datum plane. For tide waters the average sea-level is also taken as the reference. In some cases automatic tide-gauges are kept in operation for one or more years to determine an average sea-level.

The velocity of water currents in large streams is ascertained by means of a current metre, several styles being in use. The flow of the water in small streams is best determined by means of a weir.

Photographic Surveying.—The use of the camera in surveying is comparatively recent and, though its use is restricted in many ways, it has come into quite general use. It may be called a successful rival to the plane-table. Photo-surveying has been used with success in Italy, India, France, United States and Canada. In this latter country it has supplanted the plane-table almost entirely.

The advantages of a photo-transit are that with it more rapid and cheaper work can be done than by any other means. The results, however, are not as satisfactory as with the plane-table. The photo-topographer must have a thorough knowledge of perspective drawing, descriptive geometry and photography. The instrument used consists of a compass or a horizontal, graduated plate with a vernier, to which is attached a camera having a sensitive level and a means of very accurately measuring the focal length at the time each view is taken. If a box camera having a universal lens is used this latter requirement is not necessary. There is also attached to the top or side of the camera a telescope having stadia wires and a vertical circle. Some styles have a scale so placed in the box that it is photographed on the plate when the view is taken. In any case four projecting needles or two cross-wires are so placed in the box that they will make the horizon line and line of sight in the developed negative. The stadia rod is also photographed as a part of the record. The topographical map is drawn in accordance with the principles of perspective drawing and descriptive geometry, from measurements taken from the photograph, the compass bearing and stadia measurements being taken into account.

Plane-table Surveying.—A plane-table consists essentially of a drawing board mounted upon a tripod together with an alidade, an alidade being a graduated ruler carrying a telescope. (Fig. 3). A graduated vertical circle for measuring vertical angles is attached to the telescope, and stadia wires for measuring distances are often inserted in it. In operation the drawing board is covered with a sheet of drawing paper and the alidade telescope sighted consecutively to the various objects which are to be represented in the drawing. Pencil lines are drawn on the paper along the edge of the ruler at each sighting. The plane-table is then set up over another station whose relative position has been fixed by survey with respect to the first station, and sights taken to all the points sighted from the first station. The pencil lines will intersect at the points which represent the respective objects. Stadia readings are often taken with the alidade telescope, the true elevation and horizontal distances being taken from a slide rule constructed for that purpose. The plane-table is much used by the United States Coast Survey and the United States Geological Survey, as more topographical work can be done in less time by its use than by any other means except photo-topography. Errors in azimuth are impossible and more complete work can be done by making the drawing in the field than by plotting from field notes in the office.

Railroad Surveying.—Railroad surveys are either preliminary, for the study of the terrain, or for the purpose of actual location. A preliminary survey is often nothing more than a topographical survey of a comparatively wide strip of country through which it is expected to run the line, a paper location being made in the office and the location survey of the paper location afterward made upon the ground. While a topographical survey gives little or no information regarding cuts and fills it is of great value in deciding upon the most advantageous location.

Briefly stated a railroad location survey consists of a survey of curves, the tangents joining them and the grades. Tangents and curves are laid out with a transit, the grades and cross-sections being worked out with a level. From the cross-section field notes the cubic yards of earth or rock in the cuts and the volume of the fills is computed in the office. The grade line is so located that the material taken from the cuts will furnish enough material to make the fills. All straight portions of a railroad are called tangent, and the curves are surveyed as the sides of an inscribed polygon of equal sides, each side being 100 feet. (Fig. 6). The degree of curve is the angle at the centre (of the circumscribed circle) subtended by a chord of 100 feet. The length of curve, ℓ, is the sum of the sides of the inscribed polygon. The central angle, θ, is the angle at the centre included between the radii which pass through the tangent points. It is equal to the external angle of the polygon, that is, the deflection angle of the tangents. The tangent distance, T, is the distance from the vertex to
either tangent point. The conditions are such that in any railroad curve:

\[
\begin{align*}
1. \sin \frac{1}{2}D &= \frac{C}{R} & 4. \sin \frac{1}{4}d &= \frac{\sin \frac{1}{2}D}{100} \\
2. T &= R \tan \frac{1}{2} \Delta & 5. R &= T \cot \frac{1}{2} \Delta \\
3. L &= 100 - \frac{\Delta}{D}
\end{align*}
\]

By means of the above and other formulas all the elements of a railroad curve can be computed. Where tracks are to be laid especially for trains of certain speed it is the practice to lay out compound curves approaching closely the parabola, in order to make a more gradual transition from tangent to curve. When passenger and freight trains run upon separate parallel lines the outer rail of the passenger line is made higher than the outer rail of the freight line, to better counter the higher centrifugal force at the greater rate of speed. There are several methods of surveying a railroad curve: by tangent offsets, by ordinates from a long chord, by middle ordinates, by offsets from chords produced and by deflection angles. Circumstances determine the method to be used. Tables are published giving the formulas and other information needed by the railroad surveyor.

**Leveling.** Ordinary leveling is usually done with either a "Dumpy" or a "E" level, the latter being favored by American engineers. The accuracy of the "E" level is due to its construction, which permits the telescope to be reversed in the Y's. Some levels have stadia wires inserted for reading distances in some cases these are so placed that they can be blown out of focus by revolving the eye piece, thus making it impossible to make an error by reading a stadia wire instead of the central cross-wire. In order to increase the clearness and sharpness of vision, levels are often rendered "inverting" by omitting one lens. Ordinary leveling rods are made to telescope that is, lengthen or shorten — and are usually graduated into feet, tenths and hundredths of feet, but they can be read to thousandths of a foot by the aid of a vernier attached to the target. In precise leveling three methods are practised by the United States government, depending upon the instruments used. The United States engineers employ the "Kern" level and a "speaking" rod, the United States Coast and Geodetic Survey a peculiar instrument called a Geodetic level, which requires lengthy and expensive computations. The United States Geological Survey employs a modification of the ordinary Y level and either "speaking" or target rods. In precise leveling the fore and back sights must be taken at the same distance, otherwise a correction for curvature of the earth must be applied. One method of checking a line of levels is to level back over the same line of pegs. Another and a better check method is to employ two rods and make a check in a nest. In one levelman, two independent lines of turning points being run. Precise level rods are usually non-telescopic; that is, made in one piece, and the wood is heated and then paraffined. Graduals are sometimes on strips of metal countersunk into the wood. The limit of permissible error United States Coast and Geodetic Survey is 0.02 × √distance in miles, the product exceeding in feet.

**Solar Attachment.** This is an instrument which may be attached to a compass or to an instrument in determining the meridian, and time by observations made on it. There are various forms of manufacture by various firms and the Smith being those most widely used. The solar is usually seen on the transit telescope and it is used at time of day, the early morning, late evening and noon hours being avoided for reasons of lengthly to be explained here.

In order to determine the true meridian declination of the sun at the time of observation. A solar ephemeris or nautical almanac will give the sun's declination at Greenwich, England, for each day of the year. The surveyor must correct this declination for longitude (q.v.), hours from noon, a fraction of a degree, the observation refraction correction varies with the latitude (q.v.), hours from noon and declination of the sun. Having found the declination needle, the compass box is moved so that the needle at N. and S. in which will indicate true bearings.

S. SURVEYING, Marine. See Surveying.

S. SURVEYING INSTRUMENTS. Instruments used in the business of surveying fall into two general classes: those used in field work and those used in recording the work on maps. In both classes there are objects to be attained, and suitable instruments are provided for each—the marking of the measurement of lines and the measurement of angles.

In field work the "pin" is the instrument used for the temporary location of a point. It is made of stout iron wire, or a steel wire, about eight inches long, with a ring turned at the top. To go around it goes one levelman, two independent lines of turning points being run. Precise level rods are usually non-telescopic; that is, made in one piece, and the wood is heated and then paraffined. Graduals are sometimes on strips of metal countersunk into the wood. The limit of permissible error United States Coast and Geodetic Survey is 0.02 × √distance in miles, the product exceeding in feet.

satisfaction within a certain range of tempera

atures, in which the metal does not expand in

length. For measuring small vertical distances, as
stadia wires is often added to the cross-hairs of the telescope, so that the distance of the leveling rod may be computed by taking a second reading above or below the level line at the time when the level is fixed. An ingenious device renders the stadia wires invisible when the cross-hairs are being used, and vice-versa. A small pocket level known as the "Locke Level," is of great usefulness in reconnaissance work. In this instrument the bubble tube is attached to the top of the tiny telescope, the upper part of which is cut away, and a semi-circular mirror at 45 degrees placed beneath it in the telescope. The image of the bubble in the mirror decides when the instrument is held in a true level position, and at the same moment the point at which the level line strikes the leveling rod is in plain view.

For the measurement of angles in the field the commoner instruments are the magnetic compass and the transit. The former depends upon a continual reference of the direction of a line to the magnetic north-and-south line indicated by a magnetic needle swinging in a compass box, the rim of which is graduated to 15 minutes of arc, from which the angle can be very closely estimated to five minutes. By an attachment to the compass it may be made a solar compass, a necessity where the principal lines of the survey are referred to the true meridian, as in government surveys of the public lands. The compass may be still further improved by the addition of a telescope, which may be clamped to the rear sight, and this telescope may have a large bubble tube, making it available for running levels, and it may also carry a vertical circle for measuring vertical angles.

The transit is the engineer's instrument of precision for angular measurements. Its essential factor is the plate, from five to seven inches in diameter, bearing graduations of exquisite accuracy, to 30 minutes of arc in the smaller instruments and 20 minutes in the larger ones. Verniers are affixed at opposite sides of the plate by which the angular measurement may be made to 30 seconds in the one case or to 20 seconds in the other. The telescope which carries the line of sight with the intersection of cross-hairs is often fitted with stadia wires also, so that the tangents of the distances may be measured upon a leveling rod. A long bubble tube enables the engineer to use the transit for all ordinary leveling work. It is not uncommon to have a four-inch vertical circle attached, carried on four arms, and reading to single minutes. A solar attachment, consisting of three arcs of circles, on which the altitude of the place, the declination of the sun and the hour of the day may be set off, converts the instrument into a solar transit. Where a vertical circle is a part of the instrument, this serves for the latitude arc. The transit shown in the illustration is equipped with the popular Saegmüller solar attachment mounted above the primary telescope. A special form of the transit for mining engineers has the axis of the telescope extended beyond the standard at one side, and a second telescope mounted upon it so that a sight may be made directly downward. For very accurate and extended work, as in geodetical work, the telescope of the transit is sometimes 36 inches in length, the horizontal graduated circle 36 inches in diameter and the vertical circle 24 inches in diameter.

The plane table is practically a drawing board, usually 24 by 36 inches. In its simplest form the ruler or "sampling" carries sights at the ends by which the direction is obtained, the line of this direction being then drawn along the ruler upon a sheet of paper attached to the board. In the better class of instrument the sights are replaced by a telescope, which sometimes carries stadia wires for measuring distances, a compass box for orientation and short vertical arcs for measuring tangents which cannot be covered by the stadia wires. The plane table is of use chiefly for surveying topographical details upon the map by ordinary surveying methods. The plane table shown in the accompanying illustration is equipped with reds for carrying a continuous roll of drawing paper. See Surveying.

SURVEYS, United States Governmental. From an early period in its history the government has made provision for exploring expeditions of various kinds, mainly in the vast region west of the Mississippi which for many years was a but little known wilderness. Some of these explorations were for military routes to the west and later came surveys of public lands. The first official surveys were made by a geographer attached to the Continental army in the Revolution and in 1781 Thomas Hutchins (q.v.) was attached to Greene's division (Southern) as geographer. After the Revolution he was retained to supervise surveys of the Western lands and continued in office until his death in 1789.

The earliest governmental explorations, the West could hardly be regarded as surveys, although many of them prepared maps which added greatly to knowledge of a little-known region. Positions were determined astrue.
ically, and route maps were the principal products. The first of these was the Lewis and Clarke expedition sent out by President Jefferson in 1803. One of its products was a map of the country between Lake Superior and the Pacific Ocean between the 39th and 49th parallels. Major Z. M. Pike's expeditions in 1805-06 and 1807-08 explored Mississippi and the Arkansas and Red rivers were fruitful of geographic results. Major S. H. Long's expedition from Pittsburgh to the Rocky Mountains in 1819 and 1820 was under order of the Secretary of War. In 1836, a party under the command of Lt. C. Brown made another journey to the Great Lakes and the source of Saint Peter's River. Sextant and pocket chronometer were used, distances were estimated and courses were taken by compasses. The most elaborate early survey was that of J. C. Brown of a road from Osage to Topeka in 1825-27. Chain compass and a good sextant were used and a large scale map prepared. Similar to it are the surveys by R. Richardson of a road from Little Rock to Fort Gibson in 1826, and a survey by Major J. W. Albert of a military road from Fort Smith to Fort Leavenworth. In 1832 Lieutenant Allen on the Schoolcraft expedition made an excellent map on a scale of 5.75 miles to an inch, of the head of the Mississippi Valley but all the distances were estimated. He was the discoverer of the source of the great river.

The Bonneville expedition in 1832-36 was not under governmental authority although Bonneville was an army officer. The Wilkes expedition in 1840 surveyed part of Columbia River. The first of the early expeditions which could be regarded as a geological survey was made by Featherstonhaugh in 1834 to the Ozark region. The following year his observations were extended along the Couteau des Prairies between the Missouri and Minnesota rivers. In 1838 Nicollet was sent by Colonel Abert of the United States Army Engineers to make a map of the hydrographic basin of the Mississippi River. In 1839 and 1848 D. D. Owen made surveys of mineral lands of the Northwest extending to Lake Superior and covering an area of 57,000 square miles. These surveys were made for the United States Land Office. In 1847-48 C. T. Jackson and J. D. Foster and J. W. Whits and others, operating under orders of the Secretary of the Treasury extended this work in the copper district of the Lake Superior region.

Corps of Engineers, United States Army.

—A large amount of surveying was done by the topographical engineers of the United States army. The first notable expedition under that bureau was N. Nicollet's explorations of the basin of the upper Mississippi River in 1836-40 which resulted in a map which is regarded as a most important contribution of American geography. His surveys were largely instrumental and he used a barometer for ascertaining elevations. The Fremont expedition in 1842 resulted in a valuable map on the millionth scale, of the country from the forks of Platte River to South Pass between the 43rd and 45th parallels. Expeditions by Fremont in following years 1843-46 extended his observations westward to the Pacific Ocean and the surveys made were the basis for important new maps.

The following is a list of some of the more notable army expeditions and surveys from 1836 to 1879 (excepting the surveys for Pacific railroads which are noted on following page):

Black Hills.
Carroll, Mont., to Yellowstone Park.
Big horn and Yellowstone Valley.
Routes in Wyoming.
Geographical Surveys west of 100th Meridian.
There were also many reconnaissance trips and explorations for roads which could hardly be called surveys. Some of the maps were not published but remain on file in the War Department.

Hills Survey.—In 1874 Capt. W. Ludlow made expeditions through the Black Hills of South Dakota with N. H. Winchell as geologist. The results were given in a quarto volume issued in 1875. Later the Indian Bureau took an expedition under W. F. Jenney and H. E. Newcomer to investigate reports of gold in these hills and a quarto report with folio of maps was published by the Survey of the Rocky Mountain region.

Pacific Railroads.—In 1853 the War Department began a series of explorations for routes for railroads across the Far West. The expeditions were conducted by army officers but had topographic and geologic assistants, who made surveys of various kinds. Among these geologists were Jules Marcou, Thomas Antisell, J. S. Newberry, W. P. Blake and James Schiel. The routes surveyed were not far from the several transcontinental railroad lines of to-day. The results were published in 13 topographic memoirs, not all of which had geographic results of the surveys but a large amount of information on natural history, resources, etc.

International Boundaries.—The boundaries of the various States have been surveyed by various organizations. In 1818 surveys were begun on the northern boundaries of New York, New Hampshire and Maine by United States army engineers. In 1822 (?) the Northwest Boundary Commission, appointed under the Treaty of Ghent, made a survey of the boundary in the region about the outlet of Lake Superior, and in 1857-61 the United States Commission working under direction of the State Department surveyed the boundary west from longitude 110°. In 1872-75 the United States Boundary Commission under the State Department surveyed the Canadian boundary along the 49th parallel and a narrow strip of contiguous country from Lake of the Woods to the Rocky Mountains, crossing the border with the survey from the west. The Louisiana-Texas line survey in 1840 was made jointly by engineers of the United States army and surveyors appointed by Texas. The results are in Senate Ex. Doc. 190, 27th Congress, 2d Session. Considerable boundary surveying has been done by the Coast and Geodetic Survey. The Mexican Boundary Survey was made by Maj. W. H. Emory in 1853-56 and its results were published in two quarto volumes which included geological observations by Parry and Schott. Detailed remapping of this boundary in 1889 was done by a joint International Boundary Commission consisting of three Mexican members, two army engineers and a member of the United States Coast Survey. The result was a folio of maps showing topography and profiles from El Paso to the Pacific. The southern boundary of Kansas was surveyed by Lieut.-Col. J. E. Nicollet in 1833 and the Texas boundary in 1858-59 by a commission organized by the Interior Department.

Lake Survey.—A survey of the Great Lakes was made by the War Department (corp. of engineers) in 1841 to 1861. Very detailed charts (170,000 square miles) and a chart of the Great Lakes were published by the Survey of the Rocky Mountain region.

Hayden Survey.—The survey under F. V. Hayden began in 1867 for the General Land Office and its work was in Nebraska Territory, but it was not until 1871 that it began much surveying. In 1873 it became the United States Geological and Geographical Survey of the Territories and in the next five years covered 170,000 square miles of survey and topographic and geologic mapping, mostly in Colorado, Wyoming, Idaho and Montana. James T. Gardner was chief geographer and A. D. Wilson and Henry Gannett were in charge of parts of the work. The principal geologists were A. C. Peale, W. H. Holmes, A. R. Marvine, F. H. Endlich and F. V. Hayden. Twelve annual reports and a series of quarto memoirs were published.

Fortieth Parallel Survey.—This survey was organized and conducted by Clarence King under direction of the chief of engineers, United States army, operated from 1867 to 1872. It prepared topographic (contour) maps and geological map of a wide strip of country contiguous to the 40th parallel west of the 106th meridian. The geological work was by Clarence King, S. F. Emmons, Arnold Hague and James D. Hague. John D. Gardner was in charge of topographic work. The results were published in seven quarto volumes and a map of the Wheather Survey. From 1869-79 extensive explorations were made in the West under direction of Capt. G. M. Wheeler of the United States army engineers. The title of the organization was United States Geographical Surveys west of the 100th meridian. Many hachured topographic maps were prepared of parts of Arizona, Utah, New Mexico and Colorado and the geology of various regions was mapped by G. K. Gilbert, A. R. Marvine, E. E. Howell, J. J. Stevenson, I. C. Russell and others. The principal results were published in three quarto volumes issued in 1873, 1881 and 1889.

United States Geological Survey.—In 1876 there were four geological surveys in progress, the Hayden, King, Wheeler and Powell with some duplication of work, a condition which aroused so much criticism that Congress referred the consideration of the continuation of the work to the National Academy of Science. They recommended the substitution of a single organization for the topographic and geologic work, and accordingly in 1877 Congress created the United States Geological Survey (q.v.) as a bureau of the Interior Department. This survey has been continued by annual appropriation (about $1,500,-
00 in 1917). It has made detailed topographic maps of 40 per cent of the area of the United States. Large areas have also been mapped geologically, considerable public land classified in various ways and water resources determined. The maps are on various scales and sold at cost of paper and printing, most of them by the survey. Many of the geological reports are for gratuitous distribution. Two hundred and eleven folios of the Geologic Atlas of the United States have been issued which sell from 25 to 75 cents each.

Reclamation Service.—Many detailed surveys have been made by the Reclamation Service in connection with its various projects, and many suggested ones. Some of the resulting maps have been issued in the various annual reports of the bureau and others are filed.

Isthmian Surveys.—Many surveys have been made by parties sent to the Central America and Panama by the United States government to obtain data for canal routes.

General Land Office.—The General Land Office created in 1812 (see PUBLIC LANDS) and since 1849 a bureau of the Interior Department, has surveyed a large proportion of the public lands in the States west of the Mississippi River, except Texas, and also Ohio, Illinois, Indiana, Florida, Alabama, Wisconsin and Michigan. Many of the State lines were run by the Land Office. In the surveys by this bureau public lands are divided into townships six miles square, comprising 36 sections one mile square, the latter divided into quarter sections of 160 acres and in some cases, minor divisions, a system devised by Lieutenant-Colonel Mansfield in 1803. The enclosing lines are due north and south and east and west and owing to convergence of meridians and varying length of parallels at different latitudes the divisions are only approximate. The townships are numbered east and west from prime meridians, and north and south from standard parallels. The sections, ordinarily a mile square, are numbered thus:

<table>

Thus, for instance, a piece of land is designated NW3/4 Sec. 28, T. 19 S., R. 28 W. New Mexico. Farther subdivision is indicated by ¼, ½ sections, and odd areas as lots. The maps are prepared on a scale of two inches to one mile and in most cases the configuration of the land is represented by hachures excepting in later work in a few Indian reservations where contour lines have been used. This mapping covers most of the smooth surfaced or rolling lands but large areas of mountain lands are not yet subdivided. The maps are issued but held in file in the general land office and local land offices in various public land States. The bureau does, however, issue general maps of the States and of the United States compiled largely from its own surveys.

Coast and Geodetic Survey.—The work of mapping the coast of the United States was initiated by Congress, 10 Feb. 1807, on recommendation of Thomas Jefferson, with an appropriation of $50,000. F. R. Hassler was its first superintendent, beginning work in 1816 and continuing to 29 April 1818 as a bureau of the Treasury Department. The surveys were then continued by the United States army engineers and by officers of the navy until the bureau resumed operations again in 1832 under the Navy Department with Hassler again as superintendent. On reorganization late in 1843 A. D. Bache became superintendent and he continued in charge until his death in 1867. Pierce, Patterson, Hilgard, Thorn, Mendenhall, Dulfield, Fritchett, Tittmann and superintendents. The geodetic work or determination of the form of the earth was made an additional function of the survey in 1878. The survey has prepared charts of the coasts and exterior waterways of the United States and of parts of its possessions, and mapped more or less of the coast, the District of Columbia and other areas. Many special reports on geodesy, tide tables and scientific researches of the bureau have been issued. The charts which are issued in sheets of various sizes and scales are sold at low rates directly by the bureau and by local agents in seaboard cities.

Mississippi and Missouri River Commissions.—The Engineers corps, War Department has made a detailed survey of the Mississippi River and of its principal tributaries, showing topography of the shore, 1876-84. These surveys were intended primarily for guidance in the many engineering problems connected with improving the waters for navigation, a task on which the government has expended over $150,000,000 up to end of June 1916. The War Department has made special surveys for many river and harbor improvement projects.

Hydrographic Office (q.v.).—To this branch of the Navigation Bureau of the Navy Department is entrusted the preparation of many kinds of data relating to navigation. Numerous maps are produced in many cases based on original surveys.

Forest Service.—The Forest Service of the Agricultural Department has made surveys in most of the Forest Reservations in some cases with detailed representation of topography and distribution of various kinds of timber. A series of atlases has been published and many maps are on file in the various offices of the bureau. Some work of this kind was done by the United States Geological Survey in 1897-1900 and many maps were published in annual reports and professional papers. Since 1897 this survey obtains data as to forested areas in all districts mapped geographically.

Soil Surveys.—The Agricultural Department has made surveys of soils in many parts
of the United States, publishing the results on the detailed topographic maps by the United States Geological Survey. These soil maps are issued for gratuitous distribution.

Biological Survey. The Agricultural Department is also conducting a survey to ascertain the geographic distribution of animals and plants.

N. H. DARTON,
United States Geological Survey.

SUSA, soo-sâ, Persia, capital of the province of Susiana or Elam, on the Chaoesp River, 50 miles west of Shushtar, was one of the celebrated cities of the Old World, renowned in Biblical history. Shushtar, meaning lies is, is alluded to in the Old Testament and on cuneiform tablets of Assyria. It has a rectangular form without walls, but possessed a strongly fortified citadel, which enclosed the stately palace and one of the most important treasuries of the Persian kingdom. Numerous rivers water the plain in which it stands, some of which partly surrounded the ancient city. All the Persian kings, beginning with Darius I erected beautiful palaces, the remains of which belong to the most magnificent ruins of Asia. It was the seat of Esther's intrigues, and it was here that Esther's instructions were delivered. Daniel saw the vision at Shushtar, and here he was buried. Consult Billerbeck, 'Susa' (Leipzig 1891); Dihalayou, 'L'Acropole de Susa' (Paris 1888 92); de Morgan, J., 'Fouilles à Susa' (Paris 1900).

SUSANNA, soo-zân'a, the Jewish woman who figures in the book of Susanna, as the intended victim of two elders who obtained her condemnation to death on a false charge. The prophet Daniel proved her to be innocent, and obtained a reversal of the sentence. The date of about 600 B.C. is ascribed to the event. See Susanna, Book of; Bible.

Suspension, in canon law, a censure of which a clergyman is forbidden to exercise his order or to enjoy the fruits of his benefice. Partial suspension inhibits a cleric from the exercise of his spiritual functions, or from the administration of his benefice, or only from a part of his sacred functions: for example, a bishop may be suspended from ordaining, and yet be perfectly free to govern his diocese. Entire suspension prohibits all use of order, jurisdiction or benefice. In the English canon law, as in that of the Roman Catholic Church, a suspension is removed by absolution, by revocation of the censure by the person inflicting it or by dispersion.

Suspension Bridge. See Bridge.

Suspension Railway, a railway in which the carriage is suspended from an elevated cable or track. See Monorail.

Susquehanna, Pa., borough of Susquehanna, on the Susquehanna River and on the Erie Railroad. It is 38 miles north of Carbondale and 23 miles southeast of Binghamton, N. Y. It has machine shops, chemical works and manufactures of washing machines and metal ware. Pop. 3,478.

Susquehanna, süs-kwê-hân'a, a river formed by two branches, an eastern or northern and a western, which unite at Northumberland in Pennsylvania. The eastern branch, which is considered the main stream, issues from Lake Otsego in New York, and has a length of about 250 miles. The western branch rises in the western slope of the Allegheny ranges, and flows very circuitously east-southeast for about 200 miles. The united stream flows south and southeast, passing Harrisburg, Wilkesbarre and Binghamton, N. Y., enters Maryland, and after a course of about 150 miles flows into the northern extremity of Chesapeake Bay. The navigation was much obstructed by rapids, but by constructing canals the river has been made navigable for a considerable distance from the Chesapeake.

Susquehanna Company, The, in American history a land company formed in 1754, chiefly by Connecticut farmers, for the colonization of the Wyoming country. By a treaty with the Five Nations, 11 July 1754, an enormous tract of country was purchased for $10,000. It began at the southern boundary of Connecticut and followed in a northerly direction the course of the Susquehanna to northern Pennsylvania. In 1783-86 many disputes arose between the Susquehanna Company and the Pennsylvania claimants of the territory. This was called the "Pennamite War."

Susquehanna University, a Lutheran institution of higher education at Selingsgrove, Pa., founded in 1858. The faculty numbers 22; the average annual attendance of students is 325; tuition fees are $75 to $90; living expenses, board, etc., $175 to $220; the productive funds amount to $72,000; the total income, including tuition and incidental charges, amounts to $42,000. The college colors are orange-maroon. The library contains over 16,500 volumes. The number of graduates since organization number over 1,000.

Sussistinnako, the Spider, was according to the Sia Indians of New Mexico, the first of all beings in the lower world. He lay out the directions by drawing one line of earth from east to west, and another from north to south. Within the magic confines thus laid out he sang his magic songs and rattled his magic rattle, and as he sang and rattled people, animals, birds and insects appeared at his call. He created two mothers, who were the mothers of all; then he divided the people into clans, after he had created the earth for them, and he made the Cloud People,
ing People, the Thunder People and the People, and he commanded them or the people of Haarts (the earth). The world into three parts: Haarts (upper plain); and to the Clouds (rainbow) he gave the Middle Plain. This had been done he had the two others create the sun, the moon and the night.

SUSTENTATION FUND, the name specified in the Presbyterian denomination fund for the support of poorer All important religious bodies have this character. The object is to en- sure gifts of their own means properly a pastor or minister, to benefit of religious services.

ERLAND, Alexander, Canadian clergyman: b. Guelph, Ontario, 17; d. 1910. He learned the printer’s trade. studied for the ministry and in 1859 died a preacher and stationed at He removed to Therold in 1861 and preached at Drummondville, Ham- Ville, Toronto and Montreal. He was of the Conference in 1870-71, and unior of the Methodist churches in Canada. was secretary and treasurer of the Church. In this capacity he buddy tours of Canada, and in 1879 was a campaign to raise $75,000 for the clearing of the missions depart- ment and success to the work. ‘A Summer in Prairie Land’ (1892).

ERLAND, George, United States clergymen. Buckinghamshire, England, 25 March 1851 came to the United States with his 1864, received his academic educa- tion and studied at the University of in 1882-83. He was admitted to the 83 and engaged in practical at Salt Lake City. He was elected to the Utah Republican party in 1896; served in 1901-03 and in the United States 1905-17.

ERLAND, Howard, United States near Kirkwood, Mo., 8 Sept. 1865. was graduated at Westminster Col- on, Mo., studied law at Columbia (Washington) University, but did not pursue an engineering career. In 1889-90 Mr. Suther- editor of the Republican of Fulton, from 1890 to 1893 served as clerk of population division of the 11th in 1893 he removed to Elkins, W. Va., 10 years he was connected with the in coal and railroad interests, be- fore general agent land. For has engaged in coal and timber land on his own account and is president of the Newbrough Land Company of Valley In 1882 he fought in the wars of the Buddhist story and system. The Christian, T. W. Rhyds Davis, gives the dates of Buddha’s life of 80 years about 500-420 B.C.

SUTTEE, sū-tē’, in India, a term applied to the self-immolation of Indian widows on the funeral pile of their deceased husbands. The origin of this practice is of considerable antiquity, but it is not enshrined by the laws of the great legislator, Manu, nor is it based on the Vedas. This practice was abolished by Lord
Hentince, governor-general of India, in December 1829, and may now be said to be extinct, though perhaps rare cases still occur. Until then the British government had permitted it, perhaps as a protest against the very religious practice of the Hindus (which the religion of Brahma also prescribes), and if notice of such resolution had been previously given to a magistrate, who was required to see that the sacrifice was public and that all the requisite ceremonies were fulfilled. The ceremonialities of a sacrifice were various and lasted from a quarter of an hour to two hours. Sometimes the widow was placed in a caviary prepared under the corpse of the husband; sometimes she was laid by the body, embracing it. If the deceased died at a distance from home, anything which belonged to the deceased — his garments, slippers, walking-staff — might be substituted for the corpse. Consult Bose, J. C., 'The Hindus as they Are' (2d ed. London 1864), and Tylor, E. B., 'Primitive Culture' (4th ed., 2 vols., New York 1903).

SUTTER, John Augustus, American pioneer: b. Kandern, Germany, 15 Feb. 1803; d. Washington, D. C., 17 June 1880. He was graduated at the Bern Military Academy in 1823 and came to America in 1834, locating at Saint Louis. Receiving favorable accounts of California he crossed the Rocky Mountains in 1836; sailed down the Columbia River and thence to Hawaii. After going to Sitka, Alaska, he cruised along the Pacific Coast and was stranded at the site of San Francisco in July 1839. During that year he established the first white settlement on the site of Sacramento. In 1841, after receiving a large tract of land from Mexico, he built a fort which he named New Helvetia on the site of the present Sacramento, Cal.; was made governor of the frontier country by Mexico, but was held in suspicion by the Mexicans owing to his friendly feelings toward the United States. In 1848, when California was ceded to the United States, he owned many thousand head of cattle, much land and other property, but owing to the discovery of gold his estates were overthrown by miners, and his workmen left him, and not being able to secure others he financially ruined. He appealed to the Supreme Court, but was not sustained. Later the legislature of California granted him a pension of $250 a month. He moved to Litz, Pa., in 1873. (See SACRAMENTO, CAL.) Consult Dellenbaugh, F. S., 'Fremont and 49' (2d ed., New York 1914).

SUTTNER, Bertha, Baroness von, Austrian author and worker for universal peace: b. Prague, 9 July 1843; d. Vienna, 21 June 1914. She was the daughter of Count Franz Kinsky, an Austrian field-marshal, who died in her infancy. She was excellently educated, traveled extensively, and in 1876 she was married to Friederich Vitus Gundacar von Suttner, the novelist, who died in 1902. She was for a time secretary to Alfred Nobel, and for the greater part of her life was an indefatigable worker for world peace. She was widely known as a writer of fiction, on social science and on a world union to ensure peace. She was awarded the Nobel Peace Prize in 1918. She wrote: 'Der Mann und Freiheit' (1882); 'Die Waffen nieder!' (1884); 'Hanna' (1884); 'Krieg und Frieden' (1891); 'Schark der Qual' (1891); 'The hanger Friedenskonferenz' (1900); 'When Thoughts Will Soar!' (1914); 'Der Kampf um die Vermeidung des Weltkrieges' (2 vols., 1917); etc. Consult her 'Memoirs' (Stuttgart 1908; Eng. trans., Boston 1910).

SUTTON, Mass., village and township in Worcester County, eight miles southeast of Worcester, on the New York, New Haven and Hartford Railroad. There are manufactures of cotton goods. Pop. town, 2,829.

SUT TUNG PO, or SOO TUNG PO, also known as SOO SHIH, Chinese poet, essayist and statesman: b. 1631-36; d. 1101. He was educated under the care of his mother and passed first on the list when he was examined for his degree. He was at various times the holder of high offices at court, but was several times banished through the jealousy of enemies. He was a brilliant writer of verse and essays, and holds a high place in Chinese literature. Consult Giles, H. A., 'Gems of Chinese Literature' (1884); 'A History of Chinese Literature' (1901).

SUTURE, a line along which two things are joined, as by sewing, etc., so as to form a seam or something resembling a seam. In anatomy a suture is the immovable junction of two parts by their margins. The sutures of the skull are the lines of junction of the bones of which the skull is composed. Various types of suture exist, as the serrated or denitied suture, the squamous or scauly suture and the harmonic suture or harmonia. Arranged according to their situation, there are coronal, frontal, fronto-parietal, occipito-parietal, and many other sutures. In surgery a suture is the uniting of the lips or edges of a wound by stitching. In zoology sutures are the outlines of the septa in the Tetrabranchiata, so named from their resemblance to the sutures of the skull. When these outlines are folded the elevations are called saddles and the intervening depressions lobes. In botany a suture is the line formed by the cohesion of two parts. If the suture formed by the carpellary leaves in a pistil face the centre of a flower it is called the ventral suture; if it face the perianth, the dorsal suture. The former corresponds to the margin and the latter to the midrib of the carpellary leaf. Consult Donaldson, 'Modern Surgery' (7th ed., Philadelphia 1914).

SUVA, soe'vā, the capital of the British colony of the Fiji Islands (q.v.). It is about 1,100 miles distant from Auckland, New Zealand. It has a population of over 1,300 Europeans.

SUVALKI, soo'val'kee, Poland, (1) capital of the province of the same name, on the Garna-Hauka, near the Prussian frontier, 152 miles northeast of Warsaw. It contains two churches, municipal buildings and a large market-place, various schools of primary and grammar grades, two breweries, etc. Pop. about 35,000. The town was taken by the German forces in 1915. (See WARS, EUROPEAN.)

(2) The province of Suvalkis lies in the extreme northeastern part of Poland. In the north is covered by thickly-wooded plains and on the Prussian frontier are forests, swamps and lakes. The fertile soil is rich there also. The chief rivers are the Niemen, Bohr, Schescheupe and Pissia. Agriculture is the principal occupation.
SUROVOROFF-RIMNIKSKI — SVEDRUP

There are numerous factories, including tanneries, distilleries and mills. There are some schools. Area, 4,763 square miles. The population is about 700,000, of whom 50 per cent are Lithuanians.

SUROVOROFF-RIMNIKSKI, soo-rohv-oft rim-myhksk-hee (Prince ITALIAN), a celebrated Russian general: b. in Moscow according to one account, in Finland according to another, 24 Nov. 1729; d. Saint Petersburg, 18 May 1800. He entered the army as a grenadier, was bravely in the war against Sweden and by his distinguished conduct during the Seven Years' War gained the rank of colonel (1762). He participated in the suppression of the Polish uprising of 1768-69, capturing Cracow in the first year of the conflict and attaining the rank of major-general. When war with Turkey broke out in 1773, Suvoroff as general of division achieved notable victories at Turtukai and Hirsuvu, and in conjunction with a force under Kainenski, completed the overthrow of the Turkish army at Kosludji beyond the Danube. Subsequently he fought against the pretender Pugatcheff, whose overthrow was largely due to his exertions, and made successful campaigns in Crimea, against Kazakhs, Kabul, and Kirghiz, and against the mountain tribes of the Caucasus. Upon the renewal of war with Turkey in 1787 he was entrusted with the chief command, and after inflicting decisive defeats upon the enemy at Kishburn, Otrchakov and Teshchani, performed the most splendid feat of arms of the entire war by effecting the rescue of the Austrian army under the Prince of Saxe-Coburg, which was surrounded on the banks of the Rymnik by a vastly superior Turkish force, which Suvoroff utterly overthrew, gaining thereby the title of Rimnikski and the rank of count. In 1790 he stormed Ismail, where his troops were guilty of the most bloody excesses. Sent in 1794 against the Polish insurgents he gained the title of field-marshal by his storming of the Praga, suburb of Warsaw, and the occupation of the Polish capital. After five years of retirement, he was summoned to take command of the Russian forces which were to cooperate with the Austrians against the revolutionary armies of France in Italy. At 70 Suvoroff was to achieve the most notable triumphs of his career. Arriving in Italy in April 1799 he succeeded within four months in driving the French from the northern part of the country, after he had defeated their armies at Cassano, 27 April, on the Trebbia, 17-19 June and at Novi, 15 August. Thereupon he crossed into Switzerland to effect a junction with a second Russian army under Korsakoff. The crossing of the Saint Gotthard pass was accomplished only after fearful hardships, with the loss of one-third of his army and all his guns. In Switzerland he found that Korsakoff had been defeated at Magenta and that the French were masters of the country. He thereupon began a retreat through the Grisons and Vorarlberg, in which he displayed some of the highest qualities of his generalship. Setting out on the way to the Rhine in April 1799, he was in-chief of all the Russian forces with the title of Prince Italieski, he lost the favor of the Emperor Paul before his arrival in Saint Petersburg, where after a short ailment he died. Consult Smith, F., 'Suvorow's Leben und Heerzüge' (Vilna 1833-34); also his 'Auto- biography,' edited by Glinka (1819); and biographies by Polevoi (1853); Spalding (1890). Consult also Macready, E. N., 'A Sketch of Suwarrow and his Last Campaign' (London 1851), and Reding-Biberger, 'Der Zehnte Suworows durch die Schweiz' (Zürich 1869).

SUWANNEE, soo-wahn-ee, a river in southern Georgia, in the Okefenokee Swamp, which flows in a winding, generally south-southwest course through Florida into the Gulf of Mexico, about 10 miles north of Cedar Keys. It is the subject of the popular ballad, 'Old Folks at Home,' beginning "Way Down on the Suwanee River." Its total length is about 240 miles.

SUWARROW, soo-wahr-ow, or SUVAROF, a group of islands in the Pacific Ocean, between Samoa and the Manihiki Islands, is generally included in the Tokelau Islands. It has important pearl fisheries. Great Britain annexed the islands in 1889.

SUYEMATSU, Kencho, VISCOUNT, Japanese statesman, son-in-law of Marquis Hirohumi Ito (q.v.): b. Bunzen, Kiitsu, August 1855. He served in the Satsuma Rebellion as a civilian official in the army under the command of the army officer and later engaged in journalism on the staff of Nichi Nichi. In 1890-95 he was a member of the Japanese House of Commons, and after he was created baron in 1895 he served in the House of Peers. He was director of the Legislative Bureau in 1896-1903, Minister of Communications in the Ito Cabinet in 1898; and held the portfolio of the Interior in the Seiyukai Cabinet in 1900-01. He served as a non-official agent for Japan in London during the Russo-Japanese War in 1904-05. He was made a viscount in 1907. He translated into English 'Genji Monogatari'; and is author of 'The Rising Sun: A Fantasy of Far Japan' (1915).

SUZZALLO, Henry, American university president: b. San José, Cal., 22 Aug. 1875. He graduated at the California State Normal School in 1895, at Leland Stanford Junior University in 1899 and took his Ph.D. at Columbia University in 1905. He was connected with the faculty at Leland Stanford Junior University in 1902-07; was professor of the philosophy of education at Teachers' College, Columbia, in 1909-15; and since 1915 has been president of Washington University, Seattle. He has edited the Riverside Educational Monographs since 1909, has lectured extensively and is a contributor to educational magazines. He was appointed chairman of the Washington State Council of Defense in 1917.

SVEDRUP, svevr-droop, Otto, Norwegian Arctic explorer: b. Harstad Farm, Helgeland, 1855. He went to sea at 17, went with Nansen to Greenland in 1888, and again in 1893, as a commander of the Fram, which he brought back to Norway in 1896. He led an expedition to the northern regions in 1898, with the intention of exploring the north of Greenland. The expedition received its financial support mostly from two himandred individuals, and the Norwegian government renovated and equipped the Fram for his use. On reaching Smith Sound, between Ellesmere Land and Greenland, he found it impossible to force his vessel further north through the ice, and sent
two expeditions to the southwest across Ellesmere Land, which penetrated a region never before explored, and found in the southern part of Ellesmere Land a large glacier district. Later in 1890 he brought the Fram down into Jones Sound, to the south of Ellesmere Land, and from there conducted a number of sledging expeditions, exploring the southern and western portions of Ellesmere Land. On the southeast coast of Ellesmere Land, north of Jones Sound, a large bay was discovered about 100 miles in breadth and penetrating into Ellesmere. On the northern side of this bay large and complicated fords are situated. On the west coast of Ellesmere Land, in about 85° W., a large system of fords was discovered. To the west of Ellesmere Land, about 130 miles north of the Parry Islands, Sverdrup discovered two islands, to the north and west of which nothing was visible but rough polar ice. He returned to Norway in 1902. The discovery of the islands and the mapping of the western and southwestern coasts of Ellesmere Land are the most important results of Sverdrup's expedition. He brought back also a valuable series of meteorological reports, and a large natural history collection. In 1914–15 he led a relief expedition to the Arctic and wintered on the shores of Kara Sea. He published 'New Land: Four Years in the Arctic Regions' (1904).

SVETLA, Karolina, Bohemian novelist: b. Prague, Austria, 24 Feb. 1830. She gained the attention of the literary critics by her first novel 'A Double Awakening,' published in 1858. She has attained high rank in Bohemian literature, many of her novels being translated into French, German, Polish and Russian. Among them are 'Laska k Isakoviči' (1860); 'Yesnicky roman' (1869); 'Kriz a potoka' (1871); 'The Atheist' (1873).

SWABIA, swä'bi-a, or SUABIA (German, Schwaben), capital Augsburg, now part of the republic of Württemberg, formerly a duchy in the southwestern part of Germany, occupying the area now covered by Baden, Württemberg and a part of Bavaria. It extended from the Rhine to the Lech on the east and from Switzerland northward to the Rhine Palatinate. It is a mountainous country, and probably the most picturesque portion of Germany. The region was known in ancient times as Alamannia, and received its present name from the Suevi, who entered it in the 5th century and amalgamated with the Alamanni. In the 10th century Swabia was raised into a duchy which continued in the house of Hohenstaufen until 1268, when it was resolved into a number of lesser principalities among whom there was continual feud. In 1488 these little states formed the famous 'Swabian League' for the purpose of securing internal peace and giving mutual aid to each other. In 1512 the emperor, Maximilian I, made Swabia one of the 10 circles into which Germany was divided, and enlarged its territory. This division continued until 1806, when the modern kingdom of Württemberg was founded. (See BADEN; WÜRTTEMBERG.) At present the name of Swabia is obtained by one of the southern provinces of Bavaria. Consult Stalin, B. F., 'Geschichte-Württemberg' (Gotha 1882–87); Schneider, Eugene, 'Württembergische Geschichte' (Stuttgart 1896). See WAR, EUROPEAN.

SWAGE (swáj) BLOCK, a heavy iron block of any size provided with notches and perforations, used by blacksmiths in shaping metal. The swage block is so arranged that it may be readily clamped in any desired position and may as readily be released whenever it is necessary to adjust the anvil to a different position. The block has tramlines or journals which engage open bearings formed on the top of the standards of the frame. The standards are connected with each other at their lower ends by bolts. Midway of their height they are connected by a clamping device which consists of a rod revolving secured to one standard and threaded into a nut in the other standard. By operating a crank on this rod the upper ends of the standards may be drawn to give an opening to the ends of the swage block and hold it from turning. Inwardly-directed flanges are formed on the standards just below the trunnion bearings, and these on being drawn inward form firm supports for the swage block when in horizontal position. The recesses lying between these flanges receive and securely hold the swage block in its vertical position. When the swage block is held at other angles the flanges sink into grooves formed in the ends of the block around the journals. The usual variety of notches, recesses, perforations, etc., are provided for assisting in upsetting bolts, shaping horseshoes and forming all other devices which a blacksmith may be called upon to make. The construction of this swage block is the extreme of simplicity.

SWAIN, swán, George Fillmore, American civil engineer: b. San Francisco, Cal., 12 March 1857. He was graduated at the Massachusetts Institute of Technology in 1877 and then studied in Berlin, Germany. In 1887 he accepted the chair of civil engineering at the Massachusetts Institute of Technology, where he remained until 1909. He also served as consulting engineer of the Massachusetts Railroad Commission and was member of the Boston Transit Commission and its chairman in 1913. In 1909 he was made professor of civil engineering at the Harvard Graduate School of Applied Science. He is the author of 'Notes on Hydraulics' (1885); 'Notes on Theory of Structures' (1893); 'Report on the Water Power of the Atlantic Watershed' (in Vol. XVII of the 'Tenth United States Census') and 'Conservation of Water by Storage' (1915).

SWAIN, Joseph, American college president: b. Pendleton, Ind., 16 June 1857. He was graduated at the Indiana University in 1883, was assistant professor of mathematics in 1883–86 and full professor, 1886–91. He was called to the chair of mathematics in the Leeland Stanford Junior University in 1891, which he held till 1893, and was president of Indiana University, 1893–1902. Since the last-named date he has been president of Swarthmore College. He is the author of numerous scientific papers. In 1913–14 he was president of the National Education Association.

SWALLOW HOLES. See SINK HOLES.
SWALLOW-TAILED BUTTERFLIES — SWAMMERDAM

SWALLOW-TAILED BUTTERFLIES, butterflies of the family Papilionidae, typical species of which have the hinder wings extended into prolongations called tails. See BURNT-SIDE.

SWALLOWS, a family (Hirundinidae) of passerine birds which are the counterpart in this order of the swifts (q.v.). This family is distinguished by the small, flat, triangular bill which has its sides gradually compressed toward the tip and the deeply cleft mouth, the margins of which are covered with small bristles or none; the nostrils rounded at the base of the bill, either exposed or covered by a scale. The wings are long, while the tail is forked in nearly all species and the outer feathers may be prolonged. The feet, although small and weak, are totally unlike those of the swifts, the hind toe being never versatile, the number of phalanges not different from that of ordinary birds and the squamation normal; sometimes the tarsi and toes are feathered. In striking contrast to the swifts many of the swallows are adorned with rich iridescent colors and sometimes the sexes differ. Anatomically the swallows are truly passerine, but the fissorial bill and mouth, together with their peculiar adaptations for life in flight, makes them one of the most clearly circumscribed and natural families of that order. Owing to the many interesting modifications of the type the genera are numerous and many of them are restricted in distribution; but the more generalized genera, like the typical Hirundo, are, like the family, cosmopolitan. About 100 species have been described. Belonging to the North American fauna are 10 species representing no less than seven genera, most of which are peculiarly American. The barn-swallow (Hirundo or Chelidon erythrogaster) is abundant throughout North America and is easily distinguished by the elongated outer tail-feathers, the lustrous steel-blue color of the upper parts and the rusty breasts. (See BARN-SWALLOW.) The cliff or eaves swallow is colored much like the barn-swallow, but the tail is shorter and only slightly forked; it makes retort-shaped nests outside of barns, etc., under the eaves, as it formerly did on the faces of cliffs.

One of the swallows which retains its original habits is the beautiful white-bellied or tree-swallow (Tachycineta bicolor). It is of a fine lustrous green above, pure white below, with a tail only slightly more forked than in the last. The tree swallow is abundant in most parts of temperate North America, but especially so coastwise where great numbers nest in holes of trees from New Jersey northward. It is one of the first swallows to move northward in the spring and is frequently forced to retreat before a belated snowstorm or cold wave, being, therefore, one of the species to which the common saying, "one swallow does not make a summer," is especially applicable. In the West a related species, the violet-green swallow (T. thalassina), is found. Another interesting member of the family is the bank swallow, which is found in Europe as well as in America. Closely resembling it is the rough-wing.

Biggest, handsomest, jolliest, most domestic of American swallows and ever ready to defend his home is the purple martin (Progne subis), a familiar species throughout temperate North America, distinguished as a genus (Progne) by the strong bill with curved edges, by the moderately-sized forked tail, and by the strong and large feet. The sexes are quite dissimilar, the male being entirely blue black, the female and young, dull sooty gray on the breast. Except in the wilds where it continues to nest in hollow trees, it takes up its abode among the habitations of men. A common practice is to hang up some old water pipes, properly hollowed, for its convenience in nest-building; and in the more settled parts considerable expense is sometimes incurred in preparing for it a suitable residence. The eggs are four to six in number and white. In the country it renders essential services by attacking and driving away crows, hawks, eagles and other large birds. Its note is loud and musical. The regularity with which this species arrives from the South is noteworthy. The western variety is distinct and another species enters the habit.

Of exotic species of swallows the Hirundo rustica takes the place in Europe of our barn-swallow. On account of its frequent use of disused chimneys for nesting places this species shares with the other most popular swallow. The migration of these birds has always attracted attention from the well-known and unvarying character of their movements. They fly southward at the end of October or sometimes sooner, to winter in Africa, some finding their way to India. The majority arrive in Great Britain in April, some stragglers later and a few coming before the great body of birds. They generally return to the nests they have constructed the previous year. The house martin (Chelidon urbica) with the tarsi and toes feathered is of small size. It is of smaller size than the common swallows, and builds its nest under the eaves of houses, in the corners of windows, etc., the nest being a hemispherical structure of clay, with a round opening for entrance. A related species is the fairy martin (C. ariel), found in South Australia, where it arrives in August, leaving again in September or October. The nest, built in some tree, under eaves or in rocks, is formed of mud, and is of flash-like shape. The nest is usually built by a number of these swallows. The wire-tailed swallow (C. riferus) of Abyssinia is so named from the presence of the two elongated tail-feathers, which, being unprovided with a web, consist of the shafts of the feathers alone, and appear as long filaments. The genus Atticora includes the white-breasted swallow of South America (Atticora cyanoleuca), which makes its nest in the deserted burrows of animals. A number of other South American swallows have similar habits, occupying the nests or holes of various birds and mammals.

Consult Sharpe and Wyatt, 'Monograph of the Hirundinidae' (London 1885-94), with bibliography and numerous colored plates; Forbush, 'Useful Birds and their Protection' (Boston 1913); Wilson, 'American Ornithology' (Philadelphia 1828); and recent works on field ornithology.

SWAMMERDAM, sw'am-mér-däm, Jan, Dutch naturalist: b. Amsterdam, 12 Feb. 1637; d. there, 15 Feb. 1680. He was educated for the ministry but turned his studies to the pro-
fession of medicine. He was devoted especially to the study of insects; and his 'General History of Insects' and other works laid the foundations of the modern science of entomology. These works include 'Tractatus de fascione usque Pulmonum' (1667; Allgemeene verhandeling van bloedeloese dierijen) (1669); 'Biblia Natura, sive Historia Insectorum in certas classes Redacta' (1737–38).

SWAMP. See Bog.

SWAMP ANGEL, in the American Civil War the popular name of an 8-inch Parrott gun, so called by the Federal soldiers. It was mounted on a battery constructed on piles driven into the swamp near Charleston, S. C., and was used in the siege of that city. It burst 22 Aug. 1863, and was sent with a lot of old metal to Trenton, N. J. The gun was rescued from its impending fate and set on a granite base on the corner of Ferry and Clinton streets in the city of Trenton.

SWAMP DEER, or BARASINGHA, an East Indian deer (Cervus duvaucelli), about four feet in height, rich light yellow in color, found in large herds in moist situations. The antlers are large, with a long beam which branches into an anterior continuation of the main portion and a smaller posterior one which is bifurcated.

SWAMP GRASS. See Grasses in the United States.

SWAMP HICKORY. See Hickory.

SWAMP LAND GRANTS. The need of reclaiming the swamp and overflowed lands within the territory of the United States was brought to the attention of Congress in the early part of the 18th century. It was not, however, until the Act of 2 March 1849 that Congress made provision for the reclamation of such lands. This Act applied exclusively to the State of Louisiana, and provided that in order to aid the State in the construction of necessary canals and drains to reclaim the swamp and overflowed lands therein the whole of such lands that may be found unfit for cultivation were granted to the State with the proviso that the proceeds of the sales of all such land shall be applied exclusively as far as necessary to the construction of levees and drains for their reclamation.

This was followed by the Act of 28 Sept. 1850 which provided for a similar grant to the State of Arkansas. This act contained a section which extended its benefits to each of the other States of the Union in which such swamp and overflowed lands may be situated.

By the Act of 12 March 1860 the provisions of the Swamp Acts were extended to the States of Minnesota and Oregon which had become the Union since the passage of the Act of 1850. The reasons assigned for these grants were the worthless character of the lands in their present condition, the unhealthful effects of these lands and the enhancement in value of the adjoining government property.

At the time of this legislation it was estimated that the area of lands involved would be about 5,000,000 acres. However, up to 30 June 1918 there had been conveyed to the several States under these grants 64,258,731.04 acres. In addition there have been granted to the States 744,385.23 acres as indemnity for lands which had been disposed of to settlers prior to the time when the several grants became effective and also a cash indemnity in lieu of lands which would otherwise have been granted, amounting to $2,095,466.70. Comparatively small additional claims are coming in under these grants.

In spite of these liberal grants of land and money, the States have not drained the great body of land actually granted and in many cases the proceeds from the sales of the lands have been used for other purposes. The same reasons for reclaiming these lands which formed the original basis for these grants, therefore, still exist and the United States government has in recent years spent considerable sums to aid in the development of plans for the reclamation of small bodies of these swamp lands. There has also been a widespread sentiment that something definite should be done to make these lands available for agricultural purposes as the area of actual swamp land in the United States is estimated at from 75,000,000 to 80,000,000 acres.

SWAMP LOCUST. See Locust.

SWAMP RABBIT, or WATER HARE. See Hares.

SWAMP SASSAFRAS. See Magnolia.

SWAMPSCOTT, swamp'skot, Mass., town in Essex County, on Massachusetts Bay, and on the Boston and Maine Railroad, about 12 miles northeast of Boston and two miles northeast of Lynn. The town contains the villages of Beach Bluff, Mountain Park, Phillips Beach and Swampscott. It is a favorite watering place, and has an excellent beach and good accommodations for transient guests. There are several churches, a town high school, district schools, a public library and several private schools. Most of the inhabitants are employed in Lynn. Pop. 7,345.

SWAN, James, American soldier and author: b. Fifeshire, Scotland, 1754; d. Paris, 18 March 1831. He came to Massachusetts at an early age, became an artillery captain, a member of the legislature in 1778, and was subsequently adjutant-general of the State. He went to Paris in 1787 where he wrote 'Causes qui sont opposées au Progès du Commerce entre la France et les États-Unis de l'Amérique' (1790). He returned to America in 1795 only to go back to France in 1798. In 1813 he was arrested and imprisoned for 15 years for the suit of a German with whom he had had business relations. Among other books of his are 'On the Fisheries' (1784); 'Fisheries of Massachusetts' (1786).

SWAN, John Macallan, English sculptor: b. Old Brentford, 1847; d. 1910. He studied at the Worcester School of Art and the Lambeth Art School and under Gérôme and Frémiet in Paris. In 1885 he received honorable mention at the Salon, and in 1889 he received the silver medal at the Paris International Exhibition. He received the first and second gold medals at Munich and the first class gold medal for painting and the first class gold medal for sculpture at Paris, 1900. Most of his sculptures are studies of animals and in representing the
cat tribe he is particularly successful in giving vivacity and vitality to the rapid sanguine advance of the leopard or tiger. His principal works are 'Leopard Running'; 'The Prodigal Son'; 'Lioness defending her Cubs'; 'Polar Bear Swimming'; 'A Dead Hero'; 'The Jago'; 'Puma and Macaw' (1900); 'Wounded Leopard'; 'Tigers Drinking,' owned by Henry Frick, New York; 'Ceylon Leopards.' In 1905 he was made a Royal Academician. Consult Baldry, 'J. M. Swan, R.A.' (New York 1905).

SWAN, Joseph Rockwell, American jurist: b. Westerville, N. Y., 28 Dec. 1802; d. Columbus, Ohio, 18 Dec. 1884. He removed to Columbus, Ohio, in 1824 and was there admitted to the bar. He was prosecuting attorney in 1830-34, and judge of the Court of Common Pleas (1834-45). In 1834 he became judge of the Supreme Court and 1859 rendered his most important decision. The United States District Court in Ohio had sentenced a prisoner for violating the Fugitive Slave Law. Under a writ from the Supreme Court of the State sought to set aside the sentence, but it was sustained by Judge Swan, who declared that the State could not reverse the decisions of the United States courts. His publications include 'Treatise on the Justices of the Peace and Constables of Ohio' (1836); 'Statutes of Ohio' (1841); 'Manual for Executors and Administrators' (1843); 'Practice in Civil Actions and Proceedings at Law in Ohio and Precedents in Reading' (1845); 'Swan's Pleadings and Practices' (1851); 'Commentaries on Pleadings under the Ohio Code' (1860).

SWAN, Sir Joseph Wilson, English inventor: b. Sunderland, 31 Oct. 1828; d. 1914. He invented the carbon process of making autotypes, and with Woodbury introduced Woodburytype. To him also is due the invention of the dry plate, which has revolutionized photography. His name is, however, best known in connection with a form of incandescent electric lamp devised by him, which was the earliest in date of many of the electric lamps now in use. His other inventions include a miner's electric safety-lamp, and various improvements in photographic printing and electro-metallurgical deposition. He was a knight of the Legion of Honor, and in 1898-99 he was president of the Institution of Electrical Engineers. He was knighted in 1904.

SWAN, a sub-family (Cygnae or Olorida) of the duck family, characterized by great size and length of neck. The swans have the legs (tarsi) short and reticulated, the front toes being strongly webbed, while the hind toe is not webbed, and has no lobe; and theoral region (between the eyes and the bill) is naked.

In the water the swans are the type of grace and beauty of figure, the long arched and flexible neck, the elevated wings, and their buoyancy and skill in turning and gliding over the surface, all contributing toward this effect. On land, however, the very posterior position of the rectrices then is awkward and slow. Unlike the fussy ducks and geese there is a calmness and dignity about the behavior of swans which has always excited admiration and has caused these birds to figure much in poetic literature. Swans are generally quiet birds and some appear to be constitutionally mute. It is also said that some possess the most powerful and sonorous voices, though none of the musical ability attributed to poets to their death song. These great vocal powers are due to the sounding apparatus developed by the coiling of the gular and in some cases the sternum, much after the fashion of the same organ in certain cranes (q.v.). Not over 10 clearly marked species of true swans are known the world over and nearly every part of the world has its one or more. These birds are strong of wing and wide ranging. No species, however, breeds in Africa. They are arranged in four or five genera.

The North American swans belong to the genus Olor, distinguished from the typical Cygnus by purely technical characters. The two species, the whistling swan (O. columbianus) and the trumpeter swan (O. buccinator) are much alike in appearance, being chiefly white, but the latter is the larger, attaining a length of five feet and a spread of eight feet. The tail contains 24 quill feathers, whereas the whistling swan has but 20. The former is the more widely distributed and the one usually seen on both the Atlantic and Pacific coasts, while the trumpeter swan is most characteristic of the Mississippi Valley, up and down which it migrates, breeding in the upper parts and wintering along the Gulf coast. The whistling swan breeds only in the far north entirely beyond the limits of the United States. It winters in considerable numbers in Chesapeake Bay and the sounds of North Carolina. They associate with wild geese and like these feed largely upon water plants. The account of their large size they are considered great prizes among gunners, but the younger birds, distinguished by the duskyness of their plumage and their less brazen voices, are preferred for table use. The nests are on the ground and are lined with dried grass and down. The two to five eggs are about four and are long and of a yellowish-white color. Except for the differences resulting from its distribution and fresh-water habitat the habits of the trumpeter swan are essentially similar.

The common domesticated or achaten, mute swan (Cygnus olor) is a native of Europe, Asia and Africa. Those of Great Britain are all of the introduced domesticated variety. The swan has, from a very early date, been especially protected both legal and regal interference. In Henry VII's reign the theft of a swan's egg was deemed an offense punishable by a year's imprisonment; and the theft of a swan itself was very severely punished. Swans at a prior date were declared to be exclusively "royal" or "king's" property; and no subject was entitled to hold possession of these birds, save under special favor from the sovereign. To such subjects as possessed the permission to keep swans a special "swan" mark was attached, and this mark was cut on the bill of the birds as a distinctive badge of ownership. The process of marking is known as "swan-upping" or "hopping," and the ceremony in the Thames on the part of the Crown and of the Dyer's and Vintners' Company takes place on the first Monday in August. At the present time but few swaneries remain, but in some places cygnets are carefully raised and bred for the market, and a few of these birds are kept for...
ornamental purposes in most large parks. Several other wild species occur in the Old World and one true swan in South America. The black swan (Chenopeis atrata) is an Australian species, first discovered in 1868; the general plumage is black, the bill being deep red, the primary wing-feathers white and the trachea does not enter the sternum. It is well known in the United States as an ornamental bird. Consult Beebe, C. W., 'The Swans' (in 'Tenth Annual Report of the New York Zoological Society,' New York 1906); Stejneger, 'Proceedings U. S. Nat. Mus.' (Washington 1882); Newton, 'Dictionary of Birds' (Vol. IV, London 1896); Grinnell, 'American Duck Shooting' (New York 1901).

SWAN, Knight of, according to a legend of the lower Rhine, a knight who comes from an unknown country in a boat drawn by a swan, delivers a prince's daughter from her hated suitor and marries her himself, and afterward is obliged to leave her since in spite of his forbidding her to do so she inquires and loves her. Godfrey de Bouillon is the hero of the story. This version is followed by the unknown author of the tale 'Lohengrin'; while Conrad of Würzburg in his poem, 'The Swan Knight,' places the incident in the days of Charlemagne, Consult Hagen, 'Die Schwanensage' (1845); Müller, 'Die Sage vom Schwanen'; Jaffray, 'Two Knights of the Swan' (New York 1910); Newell, W. W., 'Legend of the Holy Grail' (Cambridge, Mass., 1902).

SWAN, Order of, an order of knighthood created in 1440 by the Elector Frederick II of Brandenburg. Its headquarters were in a monastery on a hill near Brandenburg and in Ansbach. It was composed of members of the nobility and its object was to encourage more enthusiastic homage to the Virgin Mary, and perseverance in works of mercy. The order was abolished at the time of the Reformation, but was revived by Frederick William IV of Prussia 24 Dec. 1843 in the form of a free association of men and women of all ranks and creeds for the purpose of alleviating the moral and physical misery of others. Consult Hanle, 'Urkunde und Nachweise zur Geschichte des Schwanenordens' (1874).

SWAN MAIDEN, The. See Valkyries.

SWAN RIVER. See Australia, West.

SWANEVELT, swân'-fâlt, Hermann, Dutch painter: b. Woerden, 1618; d. Rome, 1690. He set out for Italy when very young, carefully studied the scenery of its beautiful districts and, captivated by the pictures of Claude Lorraine, became a scholar of this famous master. He equaled, or perhaps surpassed, his master in his figures both of men and animals, and was always held in highest esteem among the greatest landscape-painters. His etchings, 116 in number, partly of subjects of his own invention and partly of actual scenery, are very much admired. His pictures, even during his lifetime, brought very high prices.

SWANK, James Moore, American economist: b. Westmoreland County, Pa., 12 July 1832; d. 21 June 1914. He founded the Johnstown Tribune, 1853; was chief clerk Agricultural Department, 1871-72; secretary American Iron and Steel Association 1873-85. He is also the author of 'History of Iron in all Ages'; 'Iron Making and Coal Mining in Pennsylvania,' and over 50 tracts on the tariff question.

SWANSEA, swân'-sâ, or ABERTAWE, Wales, an important seaport, capital of the county of Glamorgan, on the right bank of the river Tawe, at its mouth in Swansea Bay, 15 miles west-northwest of Cardiff. The town contains a fine town-hall with a Corinthian façade; the Royal Institution of South Wales, including a library, museum, etc.; a large building in which are housed the public library, art gallery and schools of science and art; a grammar, technical and other schools; the general hospital, a deaf and dumb institution, a blind asylum, etc.; remains of an ancient castle dating in its present form from the 16th century, though first built in 1399; a market, and a harbor.

The harbor is an excellent one with ample modern docks. The staple industries are the smelting and refining of copper, gold, silver and pyrites, which are imported for the purpose from many countries, the manufacture of tin-plate and the working of iron, steel, zinc, nickel, lead and other metals. Chemicals, patent fuels and alkali are also made in considerable quantity, and there are flour-mills, shipbuilding yards, etc. Swansea is also a leading seaport, its imports average annual value $22,000,000, being chiefly the raw material for its metallurgical industries, wheat and other grains, sugar and timber; and its exports average annual value $30,000,000, mainly coal, coke and patent fuel, iron and iron and steel manufactures, wrought and unwrought copper and chemical products (dyestuff, sulphate of copper and carbide of calcium). The vessels annually at the port have an average total tonnage entered and cleared of about 3,800,000 tons. Swansea has municipal tramways worked by electricity, and the town is served by the Great Western, London and North-Western, Midland and some local Welsh railways. The first charter of the borough was issued to King John, and subsequent charters were conferred by Henry III, Edward II, Edward III and Cromwell. The copper industry of the town began to attain importance early in the 19th century, and since about 1830 the town has rapidly advanced in consequence of the development of this and other industries. Pop. 114,663.

SWANSON, Claude Augustus, American senator: b. Swansville, Va., 31 March 1862. He was graduated at the Randolph-Macon College in 1885 and at the University of Virginia in 1886, afterward engaging in law practice at Chatham, Va. He served in Congress as a Democrat in 1893–1905, when he resigned after re-election, and in 1906–10 he was governor of Virginia. In 1910 he was appointed United States senator to fill the unexpired term of John W. Daniel, and was subsequently elected to that office for the terms 1911–17 and 1917-23.

SWANTON, John Reed, American ethnologist: b. Gardine, Me., 19 Feb. 1873. He was graduated at Harvard University in 1896, later
SWARTHMORE COLLEGE — SWEABORG

111

studied at Columbia University and took his Ph.D. at Harvard in 1930. He has been ethnologist of the Bureau of American Ethnology, Washington, since 1900. Author of 'Contributions to the Ethnology of the Haida' (1905); 'Haida Texts and Myths' (1905); 'Social Conditions, Beliefs and Linguistic Relationship of the Tinglit Indians' (1904-05); 'Tinglit Myths and Texts' (1909); 'Haida' (1911); 'Indian Tribes of the Lower Mississippi Valley and the Adjacent Coast of Mexico' (1911). He is joint author of 'Dictionary of the Biloxi and Ofo Languages' (1912); 'Anthropology in North America' (1915), etc.

SWARTHMORE (swárt'mórr) COLLEGE, located at Swarthmore, Pa. It was founded by the liberal (or Hicksite) body of the Society of Friends, and was first opened in 1869. The main building was destroyed by fire in 1881, but was immediately rebuilt. The college now confers regularly but one baccalaureate degree, that of A.B. This was the original custom until 1874, when the practice of conferring degrees of A.B., B.S. and B.F.A. and the special degree of bachelor of science in civil engineering was adopted; in 1903 the college returned to its first practice. Courses in engineering and mechanic arts are offered, and provision is made for a special course leading to the degree of bachelor of science in civil engineering. The A.B. course includes certain prescribed studies, one major study in any one department in which three full years of college work must be completed, and electives to complete the required number of hours. The prescribed studies include English, Bible study, history or economics, at least one language and one science, and mathematics, or engineering. In the departments of biology, chemistry and physics courses are planned to prepare for the study of medicine. The degrees of master of arts and civil engineer are conferred for graduate work. Swarthmore has been from the first a coeducational college, being the second institution east of the Allegheny Mountains to offer instruction to men and women on absolutely equal terms. Though it is a small college, and not a university, it is especially well equipped for an institution of its size, especially in the science and engineering departments. It has a campus comprising more than 200 acres, bordered by the gorge of Crum Creek, and including the farm on which Benjamin West, the artist, was born. The chief buildings are Parrish Hall (the main building), Science Hall, the observatory, the two gymnasiums, the president's house and residences of the professors, Wharton Hall (a new dormitory). There are two fellowships and 17 scholarships. The productive funds amount to about $1,600,000 and the annual income to $170,000, the library contains 35,000 volumes, including the Friends' Historical Library. The students number 450 and the faculty about 50.

SWATISTIKA, a symbol of the sun in the nature-religions of Aryan races from Scandinavia to Persia and India; and similar devices occur in the art of the Mexicans and Peruvians, and on objects exhumed from prehistoric burial mounds within the limits of the United States. The Swastika consists of a Greek cross, either enclosed in a circle the circumference of which passes through its extremities or with its arms bent back thus Ω, and it is found invariably associated with the worship of the Aryan sun-gods (Apollo, Odin), it is believed to represent the sun. Consult d'Alviella, Eugène Goblet, 'La migration des symboles' (Paris 1891); de Milloué Léon, 'Les schémas' (in Annales du Musée Guimet, Vol. XXXI, Paris 1909);Wilson, Thomas, 'The Swastika, the Earliest Known Symbol and its Migration' (in United States National Museum, Annual Report, 1894, Washington 1895).

SWAT, sóát, India, a territory or district of the Northwest Frontier Province, occupying the valley of the Swat River, north of Peshawar and south of Chitral. It was well known to the ancients, but seldom visited by Europeans until the uprisings of the frontier tribes in 1895. It is a narrow valley between lofty mountains, and inhabited by industrious, liberty-loving Afghan tribes. Pop. about 40,000.

SWATOW, sów-tow', China, a treaty port in the province of Kwang-tung, situated at the mouth of the Han River, 175 miles northeast of Hongkong. The total trade of the port amounts to nearly $34,000,000 annually. The imports are sugar, tobacco, cloth and fruits. The port was opened to foreign trade in 1858. The imports reach annually the sum of about $30,000,000, and the exports to $11,000,000. Pop. 65,000.

SWAYNE, sóán, Noah Haynes, American jurist: b. Culpeper County, Va., 7 Dec. 1804; d. New York, 8 June 1884. He was admitted to the bar in 1823; settled in Coshocton, Ohio, in 1825; and was prosecuting attorney of the county in 1826-29. In the latter year he became a Democratic member of the legislature. He was United States district attorney for Ohio in 1831-41. He was an associate justice of the United States Supreme Court in 1862-81. In the latter year he resigned owing to advanced age.

SWAZILAND, swá-zé-lánd, South Africa, a native state between the Drakensberg and Lobombo ranges, on the borders of the Transvaal. Its surface is mountainous but fertile, and it is thought to contain rich gold and coal deposits. It possesses wide prairies, with latter fine pasturage, especially in winter. There are also extensive forests which contain fine timber—a rarity in South Africa. Water is plentiful, the climate is healthful. The Swazis are a Zulu tribe and were subject to the intrigues of Great Britain and the Transvaal. The Boers obtained supremacy in 1895, which passed with their conquest and annexation by England in 1902. Authority passed to the high commissioner of South Africa in 1906. The Roman-Dutch law is in force. The British resident commissioner is located at Mbabane. Area, 6,536 square miles. Pop. 107,117.

SWEABORG, svá'-bérg, or SVEABORG, Finland, a fortress and naval arsenal, three miles southeast of Helsingfors, which it defends, on a series of islands in the Gulf of Finland. The site of an ancient Norwegian fort, the fortification was erected by the Swedes in 1662 to entitle the islands "The Gibraltar of the North." The principal works occupy five islands which are connected by bridges. The island of Borgo contains the chief military departments, arsenal and school of marines; the
SWEARING—SWEDEBERG

shipping docks hewn in solid rock, powder magazine and the monument to the Swedish Field-Marshal Ehrensvärd, who erected the fortifications. The strongest fort stands on the island south from here and is called Gustavsvard. Sweaborg was taken by the Russians in 1808; in 1855 it was bombarded by the French and English allied troops. After the revolution in Russia in 1917 Sweaborg was taken by the Finnish and upon the establishment of Finland as an autonomous state it was incorporated therein. Civil pop. about 1,000.

SWEARING, Profane, the use of oaths in a light and familiar manner by way of asseveration or emphasis. As popularly understood, profane swearing involves also many terms of a gross and obscene character. Profane swearing and cursing are made punishable in England by the Act of 19 Geo. II., ch. xxi., which prescribes a graded tariff of penalties for offenders according to their social rank: for each profane oath or curse a laborer, soldier or sailor incurs a penalty of a shilling; other persons under the rank of gentleman two shillings; a gentleman or any one above that rank, five shillings. In several of the States of the American Union profane swearing is variously declared punishable by the statutes. See BLASPHEMY.

SWEAT. See Perspiration.

SWEATMEN, Arthur, Canadian Anglican archbishop: b. London, England, 19 Nov. 1834; d. Toronto, Canada, 24 Jan. 1909. He studied at the University of London and was graduated at Cambridge University in 1859. He was ordained priest in 1860 and in 1865 he removed to Canada where he became head master at Hllemuth Boys' College, London, Ontario, a position he occupied in 1865-72 and 1874-76. He was chaplain to the bishop of Huron, and secretary to the Synod of the diocese of Huron in 1872-79, and held other offices in the Church. He became canon of the cathedral at London, Ontario, in 1875 and was made archdeacon later in that year. In 1879 he was appointed bishop of Toronto, and in 1907 he became archbishop, metropolitan and primate of all Canada.

SWEATING SICKNESS, a febrile epidemic disease of extraordinary malignity which prevailed in Europe, particularly in England, at different periods toward the end of the 15th century and the beginning of the 16th. It appears to have spared no age nor condition, but is said to have attacked more especially persons in high health, of middle age and of the better class. Its attack was very sudden, producing a sensation of intense heat in some particular part, which heat afterward overspreads the whole body, and was followed by profuse sweating, attended with insatiable thirst, restlessness, headache, delirium, nausea, an irresistible propensity to sleep and great prostration of strength. The patient was frequently carried off in one, two or three hours from the eruption of the sweat. It seems to have first appeared in the army of the Earl of Richmond upon his landing at Milford Haven in 1485, and soon spread to London. This body of troops had been much crowded in transport vessels, and was described by Philip de Comines as the most disorderly that he had seen, and that he had collected probably from jails and hospitals, and buried in faith. It broke out in England four times after this, in 1506, 1517, 1528 and 1551. The process eventually adopted for its cure was to promote perspiration and carefully avoid exposure to cold. The violence of the attack was generally subdued in 15 hours. The disease was endemic in parts of Picardy, France, and in Italy, being known in the latter country as military fever. In 1906 there was an epidemic in France. It appears to be allied to influenza. Compare the epidemic of the latter disease with the armies operating in Picardy in 1918, whence it spread throughout the world. Consult Hecker, J. F. K., 'Epidemics of the Middle Ages' (London 1859) and Osler, W., 'Modern Medicine' (Philadelphia 1914).

SWEATING SYSTEM. See Factories and Factory Inspection; Factory System, The.

SWEDEBERG, svä'd-bär', afterward SWEDENBORG, své'd-nborg, Swed. svä'd-nborg, Emanuel, Swedish theologian: b. Stockholm, 29 Jan. 1688; d. London, 29 March 1772. His father, Jesper Sweedborg, was a chaplain and court-preacher to the king. In 1712 Sweedberg's paternal ancestors had been opulent miners in the province of Dalcarlia, and it is also claimed that the heroic blood of Engelbrecht, who liberated Sweden from Denmark in 1434, flowed in his veins. On the side of his mother, Sarah Behm, he descended from Gustavus Wasa, king of Sweden from 1523 to 1560. The name "Sweedberg," as well as Swedenborg, which was given to the family later when they were ennobled, was derived from "Sweden," by which name the homestead was called, and which means a clearing in the forest made by fire.

About all that is known of Swedenborg's childhood and early youth is contained in his autobiographical statements made in two letters, one to Dr. G. A. Beyer, a celebrated clergyman of Sweden, the other to Rev. Thomas Hartley, of the Established Church in England. In the former he writes: From my fourth to my 10th year I was constantly engaged in thought upon God, Salvation and the spiritual ills of mankind; and several times I revealed things at which my father and mother wondered; saying, that angels must be speaking through me. From my sixth to my 12th year I used to delight in conversing with clergymen about faith, saying that the life of faith is love, and that the love which imparts life is love to the neighbor; also that God gives faith to every one, but that those only receive it who practise that love. I knew of no other faith at that time, than that God is the Creator and Preserver of Nature, that he imparts understanding and a good disposition to men, and several other things that follow therefrom. I knew nothing at that time of that learned faith which teaches that God the Father imputes the righteousness of his Son to whomsoever, and at such times, as he chooses, even to those who have not repented and have not returned their lives. And had I heard of such a faith, it would have been then, as it is now (1769), above my comprehension.

In the second letter he says: *In the year 1710 I went a tramp of the inland parts of England, and afterward to Holland, France and Germany, and returned home in the year 1714.
SWEDBERG

In the year 1716, and also afterward, I had many conversations with Charles XII, king of Sweden, who greatly favored me, and the same year offered me an assessorship in the College of Mines, which office I filled until the year 1747, when I resigned it, retaining, however, the official salary during my life. My sole objection to my resigning was that I might have more leisure to devote to the new office to which the Lord had called me. A higher post of honor was then offered me, which I positively declined, lest my heart should be inspired with pride. In the year 1719, I was ennobled by Queen Ulrica Eleanora, and named Swedenborg; and from that time I have taken my seat among the nobles of the rank of knighthood, in the triennial Diet of the Realm. I am a Fellow and Member, by invitation, of the Royal Academy of Sciences in Stockholm; but I have never sought admission into any literary society in any other place, because I am in an angelic society, where such things as relate to heaven and to hell, and the spiritual sense of the Word, interest me more than the subject of discourse; while in literary societies the world and the body form the only subjects of discussion. In the same letter he speaks of his special mission as follows: "I have been called to a holy office by the Lord Himself, who most mercifully appeared before me, His servant, in the year 1743; when He opened my sight into the spiritual world, and enabled me to converse with spirits and angels, in which state I have continued up to the present day (1769). From that time I began to print and publish the various arcana that were seen by me or revealed to me, concerning Heaven and Hell, the state of man after death, the true worship of God, the spiritual sense of the Word, besides many other important matters conducive to salvation and wisdom. The only reason of my journeys abroad has been the desire of making myself useful, and of making known the arcana that were entrusted to me. Moreover I have as much of this world's goods as I need, and I neither seek nor wish for more."

In the year 1709 Swedenberg finished his studies at the University of Upsala. In September 1710 he went to London, where for two years he studied astronomy, chemistry, physics, mathematics and other sciences. Then he journeyed through Holland to Paris and after a full year of studies and researches there proceeded to Germany in pursuit of knowledge at the universities, returning to Sweden in 1715.

During the following five years Swedenberg wrote 21 separate treatises and works on various scientific and practical subjects. Among these were descriptions of his own discoveries and inventions in science and the mechanical arts, as the construction of air-pumps, ear-tubes, flying machines, improvement in mining and smelting ores, the building of sluices and canals, the nature of fire and color, the manufacture of salt, the regulation of the coinage, and various astronomical, geological and mathematical subjects, besides an important and original little work on 'Tremulation,' being a theory of sensation in the human body. Up to this time Swedenberg had written in Swedish for the most part, but afterward all his works were published in the Latin language.

In 1719, as above mentioned, the family was ennobled and took the name Swedenborg. In 1721 Emanuel Swedenborg set forth again on a Continental tour of 15 months, publishing the same year at Amsterdam treatises on 'Chemistry,' on 'Iron and Fire,' and astronomical and mechanical subjects. At Leipzig in 1722 he published his 'Miscellaneous Observations on Natural Things.' Having returned to Stockholm he devoted the next 11 years to his duties in the College of Mines, his office in the Diet, and in elaborating a great work on the theory of creation or cosmogony which he published at Leipzig in 1734 while on a third foreign journey. This treatise, the 'Principia,' forms Part I of his 'Philosophical and Metallurgical Works,' of which Parts II and III treat of 'Iron' and 'Copper' respectively. The same year he published 'Outlines of a Philosophical Argument on the Infinite,' etc. The next year was devoted to duties at home, and the preparation of an extraordinary work on the 'Brain.' In 1736 he left Sweden for a fourth time, traveling by way of Hamburg and Amsterdam to Paris, where he remained the following year, proceeding to Rome in 1738. The next year he returned to Paris and in 1740 published at Amsterdam the 'Economy of the Animal Kingdom, Part I.' The next year he published at the same place the second part of this remarkable work on the composition, esence and circulation of the blood; the arteries and veins, the heart and brain; the circulation in the fœtus, etc. Swedenborg's ruling aim and end in all his work now was to discover, if possible, the soul. Says he: 'Bending my course inward continually, I shall open all the doors that lead to her, and by Divine permission, contemplate the soul itself.'

'The Animal Kingdom,' a great work elaborating still further a rational and philosophical view of human anatomy, was published in The Hague in 1744. It is notable that many of the doctrines in these books, discoveries and conclusions original with Swedenborg, have since been confirmed by modern investigation, but the honor has been attributed to them. Such speculations may be mentioned, the true office of the lungs; the animation of the brain, and of its coincidence, during formation, with the systole and diastole of the heart, and after birth, with the pulmonary respiration; the vitality of the blood, etc.

In 1745 appeared at London his 'Worship and Love of God,' the last of his publications previous to the opening of his spiritual sight, when he became a seer and revelator. He records three manifestations of the Lord to him calling him to his new office. The first was in 1743 in Amsterdam during a 'preternatural sleep.' The second was at Delft in Holland in 1744 when, as he says, the Lord manifested himself in person and spoke with him. "It was a countenance with a holy expression, and such that it cannot be described; it was smiling, and I really believe that his countenance was such during his life upon earth;" the third appearance of the Lord to him, Swedenborg relates, was in 1745 in London when the Lord manifested himself again in person, commissioning Swedenborg and calling him to the office of revealing the Doctrine of the New Jerusalem. "From that time I," he writes, "I gave up the study of all worldly science and labored in spiritual things, according as the Lord
commanded me to write." Then followed two years of preparation and illumination before he may be said to have been gifted with a full state of inspiration and a perception of the inmost or celestial sense of the Word. From 1748 to 1750 the 'Arcana Coelestia' in eight vols., quarto, was published in London. This work, the first of Swedenborg's Theological and Religio-physical series, sets forth the internal sense of Genesis and Exodus as it was revealed to him, he declares, immediately by the Lord alone. Then followed (1758) 'Heaven and Hell,' describing the spiritual world and the life of man after death, as well as the happy state of the blessed as the miserable lot of the infernal. In the same year appeared 'The White Horse'; 'The Earths in the Universe'; 'The Last Judgment'; 'The New Jerusalem and its Heavenly Doctrine.' During 1757-59 Swedenborg was engaged upon an explanation of the spiritual sense of the Apocalypse, which work he left uncompleted after writing 1,992 pages. It was published in 1785-89. 'The Last Judgment' describes that event itself which, as he testifies, Swedenborg witnessed in the spiritual world in 1757. 'The New Jerusalem and its Heavenly Doctrine' teaches that the New Jerusalem means the New Church now being established both in the natural and spiritual worlds, the doctrine of which is called Heavenly because it is received by angels and will be received on earth by men of angelic minds. In 1763 appeared 'The Four Doctrines of the New Jerusalem: The Lord, The Sacred Scripture, Life and Faith,' which as revealed in the Word are fundamental teachings of the Church; and 'The Divine Love and Wisdom' treating of the Lord as the Sun of heaven, the Creator of the Universe; of the nature of the Divine and its method and order in bringing ultimate finite and human creatures into existence and being. In 1764, 'The Divine Providence,' was published, showing how the created universe is perpetually sustained and setting forth the laws of God by which he governs man in even the least things of his life to eternity. 'The Apocalypse Revealed' (1766), discloses the internal and external senses of the Apocalypse or 'Revelation,' describing the New Jerusalem as to its quality of life among all those who receive the Heavenly Doctrine in this world and by obedience to its teachings are inaugurated by the Lord into his New Church. 'Delights of Wisdom Concerning Conjugal Love' (1767-68) setting forth the laws of spiritual and eternal marriage which must exist between the souls of wedded consorts. 'Disclosing the Insanities and Horrors of Adultery together with a prescription of laws for the preservation of the conjugal quality in the mind, in the heart and in the life of the man who is unmarried but who regards marriage as a heavenly and blessed estate and condition. The Brief Exposition of the Doctrine of the New Church' (1768-69) wherein is shown the utter variance of the theological dogmas prevailing throughout what is known as the Christian world, both in the Roman Catholic and Protestant churches, from the genuine doctrine of the Scriptures. In the preparation of this work Swedenborg had especially in view the doctrine of the Christian church and he distributed the book to them and to theological semi-naries in Europe. The last and crowning prize of this series of philosophical and doctrinal works is 'The Internal Sense of the nature of the Spiritual Worship in True Christian Religion or the Unveiling of the New Church' (1771) book is presented a general view of the internal sense of the New Church, together with wonderful accounts of it and heard in the Spiritual World Swedenborg as a witness thereof. Among the writings of Swedenborg since his decease may be mentioned 'The Spiritual Diary' (1748), prising a chronicle in the form of persons and things in the Spiritual World, memorable for one reason or another either met or was in some way connected on account of his mission.

In another posthumous little work called Consumption of the Age, etc., S. explains that now is the end of the Church, the Second Advent of the Saviour, the beginning of the New Church, which is to be established by the New Jerusalem and its Heavenly Doctrine. Swedenborg, the New Jerusalem and its Heavenly Doctrine" by (New York 1858) - Swedenborg: His New Age (Philadelphia 1910) - R. W. Swedenborg, or the Mystic" (London 1903) - Trobridge, George. 'Life of Swedenborg.' (Boston 1913) - Berrine, 'Balzac and Swedenborg.' (Biblidgod Documents concerning Swedenborg's Life and Work, 1906) - Stroh, A. H., 'Abridged List of Works of Emanuel Swedenborg.' (Upsala 1910.) Edition de luxe issue Swedenborg Royal Academy of Sciences, Sweden, or Sveriges, a northern European state, forming a united kingdom, occupying the peninsula known in ancient times as Scandinavia. Sweden is between lat. 55° 20' N. and 69° 20' N.; and long. 24° E. and 21° E.; and is bounded on the north by Norway; southwest by the Skag-Ra-gat and Sound; south by the Baltic; east by the Gulf of Bothnia; and by the Torne and its affluent. The area is estimated at 173,035 sq. miles, of which 3,200 are occupied by the last.
the population in 1917 was estimated at 5,757,566, of whom 2,817,950 were males and 2,939,616 females. The average density is 33.3 per square mile. The largest cities in the country are, in order of population, Stockholm, with 1,118,823 inhabitants; Göteborg, 191,535; Malmö, 35,783; Norrköping, 55,623; Kalmar, 35,783; Gävle, 36,623; Orebro, 34,453; Eskilstuna, 30,111, and Karlshamn, 28,556.

Between 1860 and 1916 the town population had risen from 434,519 to 1,617,116, showing an increase of from 11 per cent of the total population of Sweden in the first-named year to 28 per cent in 1916; and between 1840 and 1910 the number of persons dependent on commerce and industry had increased from 108,501 to 453,39 per cent. At the present time the proportions are about equal.

**Topography.**—The coast-line, above 1,400 miles in length, is serrated rather than deeply indented; it is broken by many small inlets, having neither the width nor the tortuous length by which the fjords of Norway are characterized. The west coast is very rocky, and not seldom rises so high as 30 feet. Along the south and southeast coast low shores alternate with precipitous cliffs, which, however, are of no great elevation. As above stated many islets are scattered near the shores, and these where they form the archipelago of Stockholm are especially numerous. The whole of the upper part of the shore of the Gulf of Bothnia consists of sandy alluvial deposits, which are brought down by the rivers in such quantities that they seem destined at no distant period to convert a large portion of the gulf into dry land. It would appear, however, that alluvium is not the only agent employed in carrying on this process of shallowing, since it has been proved that the whole coast of Sweden is continually rising, the rise being greatest in the north.

The interior of Sweden is by no means generally mountainous, and its surface has far less of a highland than of a lowland character. The most elevated portion of it commences in the west near the parallel of 62°, and is continued north along the frontiers of Norway, not so much in a continuous chain as in isolated mountain-masses rising from an elevated table-land, which, where loftiest, is at least 4,000 feet, and forms the base of several summits which rise more than 6,000 feet above sea-level, and owing to their high altitude are covered with perpetual snow. Sjuhäradsberget and Kebnekaise, both in Swedish Lapland, attain a height of about 7,000 feet. Other lofty peaks are Sulitjelma and Sylffjellen, between lat. 63° and 67° on the Norwegian frontier. These mountains and their table-land slope east toward the Gulf of Bothnia, sending down numerous torrents, which in their course often expand and form chains of lakes and dreary swamps. The same slope is continued to the south of 62° N., but beside it there is a south-southwest slope of its level near lat. 59° N., on the shores of the magnificent lakes which there stretch almost continuously across the country east to west. To the south of 59° N. the country is generally flat, though in many parts finely diversified. This region has several fertile and well-cultivated tracts, but a good deal of it is covered by barren sand or stunted heaths, though recorded births numbered 121,214; deaths, 77,683; and marriages, 35,156. The same year 10,571 persons emigrated, 7,208 going to the United States. The recent increase in population chiefly affected the larger cities. In 1917 they are, in order of population, Stockholm, 1,118,823 inhabitants; Göteborg, 191,535; Malmö, 35,783; Norrköping, 55,623; Kalmar, 35,783; Gävle, 36,623; Orebro, 34,453; Eskilstuna, 30,111, and Karlshamn, 28,556.

**Hydrography.**—The rivers and lakes are numerous, the latter in particular on a large scale, giving to the scenery of the country several of its grandest features. The rivers all belong to the basins of the Baltic Sea and the German Ocean. The former receives the far larger share. To it belongs the Tornè, which, rising in the Norwegian mountains, pursues its course south-southeast for nearly 290 miles, augmented by numerous large affluents, and falls into the north arm of the Baltic Sea at Flisund just before the entrance of the Baltic. The Tornè, together with its chief tributaries, the Vete, the Fjäll, and the Skellefteå, is joined by the Viskas and the Umeå at Härnösund, and the headwaters of the Swedish part of the Tornè are united at Suntio, near the entrance of the Baltic Sea. The next in size to the Tornè is the Vänern, which flows 200 miles, and the lower 50 miles of it is navigable by river steamers. The longest and most important of the rivers on the west side of Sweden, the Västra, flows 388 miles, and is navigable below a city. The Vistula, the longest river of Sweden, enters the Baltic at Dalsland, 20 miles west of Stockholm. The largest lake is Lake Vänern (area, 2,014 square miles); the next in size Lake Vättern (821 square miles). Lake Mälaren, better known than the other large lakes, from having the capital on its shores, is also remarkable for the number of islands which so crowd its surface that it is scarcely possible to find a square mile of open water. Hjelmarn, which has both a natural and an artificial communication with Lake Mälaren, has an area of 188 square miles.

**Geology and Minerals.**—The mines of Sweden are rising in importance as rapidly as new mining machinery is being introduced. In 1916 they already engaged 48,166 persons and yielded large quantities of iron and other ores, as well as lead, silver, copper and gold. In the year mentioned the amount of iron ore mined was 1,050,000 tons, weighing 60,700; sulphur pyrites, 27,848; copper ore, 13,895; manganese ore, 8,894; silver and lead ore, 3,707; pig iron, 732,734; bar iron, 526,353. Besides, there were produced 230 tons of gold ore,
3,707 tons of silver and lead ore, and 8,894 tons of manganese ore. About a third of the country is composed of gneiss, partially penetrated by granite. Patches of porphry and greenstone, of Silurian rocks, of olitite, and of cretaceous rocks, appear in various localities. Iron not only occurs in beds of immense thickness, but also is widely scattered. It is the principal mass of most of the country. The most celebrated iron-mines are those of Danelmora in Jämsas, where the iron worked is perhaps the best in the world, and is admirably adapted for steel. The quantity produced, however, is much smaller than in some other districts where the quality is also excellent.

Climate.—The climate of Sweden varies considerably with the latitude and elevation. There is hardly any spring or autumn intervening between the heat of summer and the cold of winter, but in the north the winter lasts for nine months, in the south only for seven. Speaking generally, the climate of Sweden, though much more like the proximity of the ocean, is not to be considered as anything like the interior of the northern parts of the Russian and Asiatic continents, is much more extreme than that of our own islands, even where the two countries are in the same latitude, and experiences greater degrees both of cold and heat. Hence at Stockholm the thermometer has been known to descend 26° below zero in January, and to rise in July to the almost tropical heat of 96.8°. The climate, however, is favorable to health, and no country furnishes more numerous instances of longevity.

Forestry and Flora.—Most of the public forests, covering an area of about 19,000,000 acres, belong to the government and yield considerable timber. In the very northern extremity of Sweden fine trees of pine, fir and birch are found. These, however, occupy only occasional patches, and the true forest-land must be considered as having its limit near 64°. Below this latitude, and chiefly in the central and southern parts of the kingdom, the forests occupy at least one-fourth of the whole surface, and sometimes stretch continuously for 80 miles in length by 20 miles in breadth. Many of these, however, consist of trees of stunted growth, chiefly for domestic fuel or the supply of the smelting furnaces, and seldom of much use as timber. Forests in which oak and beech are the prevailing trees occur only in the south. The flora is of the post-glacial period, and of Finnish characteristics rather than of more southern and continental latitudes. Wild briar berries are plentiful.

Fauna.—Among the larger wild animals the wolf and bear abound in the forests, and often cause great ravages. The elk and deer are also found, but in more limited numbers. Of smaller animals the most destructive is the lemming, which at intervals of years descends in immense numbers into the low country and lays it waste. Among birds the most remarkable are eagles, capercailles and woodcocks.

Fisheries.—The rivers and lakes are well stocked with salmon and trout, but the fisheries on the sea-coast have long ceased to be productive. Herrings, which used to visit the coast of the Baltic, have for the most part entirely disappeared, though large numbers of a fish resembling herrings are taken along the east coast. About 34,000 persons find employment in the fisheries.

Agriculture.—About 9.1 per cent. of the total area is under wheat, and 13.3 per cent. is under oats and 54.7 per cent. in forest, the latter furnishing a staple industry. Only a small portion of the arable land, and that mostly in the south, is favorable for the growth of wheat; but there is now a considerable export of oats and some of other cereals to Great Britain. Until recently the grain grown in Sweden did not suffice for domestic consumption. Potatoes are grown in almost all parts of the country, and form one of the main articles of food among the lower classes. The most important auxiliary crops are beet-root for sugar, hemp and flax, the latter of excellent quality; on a few favored spots tobacco, hops and madder are grown. Cherries, apples and pears are tolerably abundant in the southern districts. The principal domestic animals are cattle, sheep and reindeer. The last supply food and clothing. In 1917 there were 447,695 farms under cultivation, the products of which form a staple export.

Commerce, Manufactures, etc.—Of all the countries trading with Great Britain Sweden is the one with which the largest amount of business is done, Germany coming next. The total value of the exports to all countries in 1916 was nearly $206,991,000, of which 53 per cent. came from the United States, the exports to Great Britain amounting to half that amount. The total imports amounted to about $194,-811,000 (United States, 27.4 per cent.). The principal exports are timber, iron, butter and wood pulp; imports, iron and steel, wrought and unwrought, coal, machinery, woolen and cotton goods. Next to agriculture the most important industry in Sweden is iron-mining. Other industries now of some importance are iron-founding and engineering, the spinning and weaving of cotton and woolen goods, paper-making, brewing, sugar-refining, match-making and glass-making. In 1917 there were 9,368 miles of railways, of which 3,268 miles belonged to the state. The public telegraph and telephone lines in 1917, 341,013 miles, belong wholly to the state. A tram service operates between Trelleborg and Sassneth in Prussia.

The mercantile marine in 1917 engaged 2,801 vessels of 1,128,435 tons burden. The tonnage entered and cleared in 1913 was 28,799,114 tons. Trelleborg is the principal port and Stockholm comes next.

Weights and Measures.—The denominations of money are the öre and the krona, or crown (silver) 100 öre (each 1/32d.) = 1 krona = 1Kr. 1Nd. The greater part of the currency, however, is in paper, which is circulating in sums varying from 5 to 1,000 kronor. The metric system of weights and measures was introduced in 1883. Among old measures are the skulpund = 14.37 lbs. avoirdupois; the centner = 100 skulpund = 93.7 lbs. avoirdupois; the nylast (100 centner) = 83.67 cwt.; the kanna = 4.6 pints imperial; the cubic foot = 11.689 inches imperial; the tuneland or acre = 1 acre 35 poles; the mile = 6,644 United States miles; the square mile = 44 United States square miles; 10 linjer = 1 tun; 10 tun = 1 foot; 10 feet = 1 stöng (= 9.74 United States feet); 10 stönger = 1 ref., 860 ref., 1 mile.
The crown is hereditary in line. The king must be a member of the Royal Church, and has to swear fidelity to the land. His prerogatives consist of the right to preside in the high court of justice, to grant pardons and pardons to treaties with foreign powers, to declare war and peace, to appoint civil and military officials, and to veto absolutely any decree of the Parliament of the kingdom. He also has a power of appointment to his ministers and officials, and the grants of the blood-royal are excluded from civil appointments. The Diet consists of two chambers, which are both elected. The upper chamber consists of 150 members, elected by 25 provincial assemblies; and the lower chamber consists of 300 members, elected by the towns. Each member serves for six years. The second chamber, elected on universal male suffrage, consists of 230 members, elected for four years; and 80 for every 10,000 inhabitants. Members are paid 1,200 kronor for each session of four months, in addition to expenses incurred. The election is by ballot, and the president of the chamber, who is elected by the council of state, is chairman of the Diet. The executive power is in the hands of the king, who acts through a council of state consisting of members, chosen from among the heads of the different departments. The eight departments are: the Ministry of Justice, the Ministry of Foreign Affairs, the Ministry of Finance, the Ministry of Education, the Ministry of Ecclesiastical Affairs, the Ministry of Agriculture, the Ministry of War, and the Ministry of Marine. The Ministry of Finance is responsible for the conduct of the government. The control of the government is exercised by the Justices of the Peace, who are responsible for the conduct of the government. The total revenue of the state is estimated at 31,000,000 kronor, and the expenditure is 25,000,000 kronor. The total budget for the year 1916 is 5,000,000 kronor. Sinking funds are provided for the payment of the debt.

The army has hitherto been composed of enlisted troops, a militia maintained by land owners and Crown domains, and a regular army. The army consists of 10 regiments of infantry, 10 regiments of cavalry, 10 regiments of artillery, and 10 regiments of engineers. The total strength of the army in 1916 was 26,572 officers, 537 non-commissioned officers, 16,370 volunteers and a contingent of recruits. The total including conscripts was 85,000 men. The naval strength includes 15 armored coast defense vessels, 4 old torpedo gunboats, 10 torpedo-boat destroyers, 45 torpedo boats and submarines.

The ethnology of Sweden, with the exception of the Laplanders and Finns, found only in the north, are of Teutonic origin, and present the original features of the race in great purity, particularly in the central and southern provinces, where they are characterized by a tall, robust stature, light hair, blue eyes and light complexion. They are active and enterprising, and manifest a marked predilection for scientific pursuits. The state of morality is on the whole favorable. Heinous crimes are few, but a great number of minor delinquencies figure in the calendar and are evidently accounted for by the far too prevalent use of ardent spirits; but a considerable improvement in respect of the consumption of intoxicants seems to have taken place in recent times.

Religion and Education. Almost all the inhabitants belong to the Evangelical Lutheran Church, which is the religion of the state, at the head of which is the archbishop of Upsala. Other religions are tolerated; but appointments in the public service can be held by Lutherans only. Education is gratuitous and compulsory. Primary education is well diffused. In 1916 there were 704,000 pupils in the elementary schools. The proportion of illiterates among recruits is 0.16 per cent. The University of Upsala (2,344 students in 1916) has done much to foster the cultivation of the higher departments of science and scholarship. There is also a university at Lund (1,341 students in 1916).

Language and Literature. See Swedish Language and Literature.

History. In the case of Sweden, as of many other countries, the industry of chronicles has supplied details about ages with which they were acquainted. These early chronicles, called Sagas, contain lists of kings at variance with each other, and state that the adventure of the kind to which the epithet heroic is usually applied, in which it is impossible to separate the legendary from the historical. The first dynasty of Swedish kings, according to the legendary chronicles, belonged to a family called Ynglings, from their founder, Freyger Ingve, the reputed grandson of Odin, from whom the family claimed to be descended. The last of them was expelled by Ivar Widfadum, representative of the Danish family of the Skoldings, also descended from Odin, who united Sweden and Denmark under one rule. This event is referred to about 630 A.D. Near the end of the following century Ragnar Lodbrok, the reigning representative of this house, fell in battle on the English coast, and his second son, Bjorn Ironside, inherited Sweden, which was again separated from Denmark.

Christianity was introduced under his grandson, Bjorn II; but it was first established by Olaf, who reigned in the beginning of the 11th century (1001–26 A.D.). Until the beginning of the 12th century the chronicles contain rival lists of kings. From the first appearance of Sweden in history two rival tribes or confederacies, both of German origin, the Goths and
the Swedes, contended for ascendency, and the confusion of the chroniclers is probably due to the mingling of the lines of separate chiefs or monarchs returning simultaneously in different districts. Emund Sleme, the last of the descendants of Bjorn, was defeated and killed by the Goths in 1056, when the two nations were united under Stenkil, the Gothic monarch. On the death of Stenkil II, in 1129, the Swedes raised a private individual, Sverker I, to the throne. To conciliate the Goths it was agreed that Erik, a descendant of Stenkil in the female line, should succeed Sverker, and that the two families should reign alternately. This arrangement, which seems to indicate that the power of the monarchs was merely that of leading chiefs, was continued, though the cause of much dissension and civil war, for several reigns. During the reign of Sverker the kingdom was divided into four dioceses (1152). Erik IX, called Saint Erik, succeeded about 1155. In his reign the Finns were conquered and converted to Christianity. Charles VI, son of Sverker, who succeeded about 1162, canonized by Knut Erikson, who succeeded in 1168. Sverker II, the son of Charles, was likewise defeated and killed by Erik X, son of Knut, who succeeded him in 1210. John I, son of Sverker II, and the last of his line, was succeeded in 1253 by Erik XI, the last of his, who died in 1260. Waldemar I, nephew of Erik, was raised to the throne by election, and founded the dynasty of Folkungaar. Waldemar made a voyage to the Holy Land, leaving his brother Magnus in regency, in 1222; on his return a civil war took place, but Waldemar abdicated in favor of Magnus in 1279 and failed in subsequent attempts to recover the throne. Magnus assumed the title of king of the Swedes and the Goths. His son, Birger II, in whose reign the conquest of Finland was completed, was expelled by the people in 1319, who chose his nephew, Magnus Snake, an infant, as his successor. He had already succeeded, in right of his mother, to the crown of Norway, which he sought to his son Haco in 1349. Scania, consisting of the two southern provinces, Malmohus and Kristianstadt, which then belonged to Denmark, yielded to him in 1332, but he restored them on annulling his son Haco to Margaret of Denmark. Magnus was deposed by the states and obliged to carry on a civil war for the crown with his son Erik, whose death again left him in possession of the kingdom; but aiming at absolute power, he was again deposed in 1365 in favor of his nephew, Albert of Mecklenburg, who had already been in possession, since 1363, of the supreme authority. Albert formed a league with Schleswig, Holstein, Mecklenburg and the Hanse towns against Denmark and Norway. He succeeded in his driving the king of Denmark out of his dominions, but was defeated by the king of Norway, who besieged him in his own capital. Peace was concluded; but Albert, aiming, like his predecessor, at absolute power, made himself master of his own subjects, who invited Margaret of Denmark and Norway, the Semiramis of the North, who had united the crowns of these kingdoms, to replace him. Albert, though supported by Holstein, Mecklenburg and the Hanse towns, was finally overthrown and returned to Mecklenburg. Margaret succeeded in 1389, and by the union of Calmar the three kingdoms were formally retaining its own constitution. Under her grandnephew Erik (1412-44) revolted underly in different districts. His rule proved oppressive, the joint was renewed 1436, but both Danes and Norway were united under Erik, who was king of Denmark. His death in 1488 (Knutson) was chosen king of Norway also acknowledged him, but off the yoke. The severance of the produced a war with Denmark. The was stormy and his subjects repeat against him. He died in 1470. The king of Denmark, had been crowned in Sweden in 1458 by the party opposite, but on the death of Knuta chose his nephew, Sten Sture, adm the kingdom. Christian attempted to session of the kingdom, but was de forced to retire. In 1483 John I, son of Christian, was recognized as king of Sweden with the virtue of the titles of the kingdom, which was divided between the Danish national parties, but Sture contrived to administration, and raised an army to俄罗斯 out of Finland. In 1499 vaded Sweden with a powerful force, which was completely defeated at Rotebro, where John conferred on him the governorship of Dalecarlia; but the Swedes again proclaimed him administrador in 1501, in 1503 and in 1510, in 1521 the Senate, and the union of Scania with the Russians. In 1499 and formed an alliance with the Swedes in order to prosecute the war of Denmark. The clergy and a large part of the Senate favored the Danish alien peasantry were strongly opposed to Sture. He died in 1512 and was succeeded by his nephew, Sten Sture the Younger. In the year Christian II succeeded to the throne. After the death of Sture Vasa, the reign of the Dalecarlia, and, having established a Lutheran religion, was crowned Protestant archbishop of Upsala, in Lutheran religion was formally est Sweden in 1521. Christian II, driven from Denmark, his title was edged by his successor, Frederick I, was declared hereditary in his house in 1560. His son, Erik XIV, reigned years. Erik was one of the candidates for the throne of Sweden, and the power of the crown. Erik created a secondary nobility, reduced the titles of Count and Baron. A war with Russia, under the protection of the Teutonic order, the acquisition of Esthonia by Sweden having subsequently been confirmed, was, in the confusion caused by insanity, insurrection, and internal disasters to the Swedes. John III, of Erik, succeeded him on his death in 1570. Sweden renounced her claims and surrendered a large part of the west coast of the Baltic. A treaty was made with a view to a
Russia. In this war the Swedes were successful in foiling the designs of Ivan IV on Livonia. Peace was concluded in 1582. John had married Catherine Jagellon, daughter of Sigismund, king of Poland, and through her influence endeavored to restore the Catholic religion in Sweden. A formidable opposition arising, headed by his brother Charles, and the queen dying, he abandoned the project. Sigismund, his son, was, however, brought up in the Catholic faith, and in 1587 he was elected king of Poland under the title of Sigismund III; John died 1592. Charles, Duke of Sodermania, who held the regency in the absence of his nephew Sigismund, endeavored to deprive him of his crown on the ground of his religion, but on the return of Sigismund with an army he was compelied to relinquish the government to him. Sigismund, on receiving the crown, returned to Poland, and left his uncle Charles in the title of Gestaupkeus to seize the crown and defeated Sigismund in the battle of Sténbro (September 1598). The states now conferred on him the title of hereditary prince, and insisted upon Sigismund sending as surety to Sweden his son Gustavus Adolphus. He was acknowledged as king of Sweden, and in 1604 Charles was acknowledged as king of the Swedes, Goths and Vandals, and his son, Gustavus Adolphus, was recognized as his successor. He took the title of Charles IX. From these events arose a war with Poland, which was not terminated by a permanent peace till 1600. Wars also with Denmark and Germany continued till the end of Charles' reign. Charles IX died 1611, and was succeeded by his son, Gustavus Adolphus, then engaged in conducting the war with Denmark. One of the first acts of Gustavus was to select as his chancellor Alex Oxenstier, who became one of the first statesmen of Europe. Failing to make peace with Denmark, Gustavus took the field in person, and nearly lost his life in the battle of Widsji; but in 1613 he succeeded through the mediation of England in making peace. The Russian throne was then vacant, and Sweden putting up the candidates for it, Charles Philip, brother of Gustavus and Ladislaw, son of Sigismund. Both had invaded the country and made extensive conquests and Gustavus granted favorable terms to Denmark that he might turn his attention to this quarter. Michael Romanoff, elected in 1613, was compelled to make peace with Sweden by the cession of all his Baltic provinces; and Sweden, which notwithstanding internal troubles had been advancing in political importance since the time of Gustavus I, now became the leading power of the North. The war of succession with Poland still continued and in 1621 Gustavus turned his arms against that country and captured Riga. The war continued for nine years, and was concluded by the six years' truce of Altmark in 1629. Gustavus retained four frontier towns of East Prussia.

Sweden was now about to take for the first time a leading part in the affairs of Europe. Gustavus had been watching the progress of events in Germany, and had determined to interfere on behalf of the interests of religion and the political rights of the Protestant princes. (For the events of this war and the effects of the intervention of Sweden in the affairs of Europe see Gustavus; Prussia; Richelieu; Thirty Years' War, and other articles.) The body of Gustavus, who fell at the battle of Lützen, was brought back to Sweden in 1632, and his daughter Christina was recognized as his successor. She was a minor, and the management of affairs devolved upon the Chancellor, Gustavus Adolphus. He concluded an alliance with the German rulers, and made arrangements to prosecute the war with vigor. His power continued absolute till 1644, during which time the war in Germany continued. At the beginning of this year a war broke out with Denmark, provoked by the scheming of the queen-mother, who was jealous of the power of Oxenstiern. Denmark was suddenly invaded by Torstenson. Christina assumed the reins of government on 5 Dec. 1644, her 18th birthday, and peace prevailed, and the treaty of Brömsebro was concluded with Denmark, which ceded to Sweden the greater part of her possessions in Götland, and exempted Swedish vessels from the sound and the lübeck. Leibnitz, 24 Oct. 1648, gave Sweden western Pomerania, the duchy of Bremen and other acquisitions in Germany, with a seat and triple vote in the diet.

The reign of Christina began under favorable auspices. She had received a masculine education, and showed great attention to business and determination in supporting her views. Contrary to the advice of Oxenstien she exerted herself to promote peace both with Denmark and Germany. She patronized learning, and drew many distinguished men to her court; but she was extravagant in her expenditure, licentious in her behavior, and soon brought herself into inextricable difficulties by the profusion with which she lavished the crown domains on worthless favorites. In these circumstances she renounced the crown in 1654 in favor of her cousin Charles Gustavus, son of the count palatine, professed the Catholic religion, and after an extraordinary career died before Rome in 1660. Each set the candidates for it, Charles Philip, brother of Gustavus and Ladislaw, son of Sigismund. Both had invaded the country and made extensive conquests and Gustavus granted favorable terms to Denmark that he might turn his attention to this quarter. Michael Romanoff, elected in 1613, was compelled to make peace with Sweden by the cession of all his Baltic provinces; and Sweden, which notwithstanding internal troubles had been advancing in political importance since the time of Gustavus I, now became the leading power of the North. The war of succession with Poland still continued and in 1621 Gustavus turned his arms against that country and captured Riga. The war continued for nine years, and was concluded by the six years' truce of Altmark in 1629. Gustavus retained four frontier towns of East Prussia.
any German power during her war with Holland. In consequence of this treaty the Swedes invaded Brandenburg in 1674. They were defeated by the elector at Fehralin, 28 June 1676. After this victory Denmark entered into a league with the elector against Sweden. In the hotly contested war which ensued Sweden was defeated by the elector on land and by the Danes at sea, but her ally was victorious. Louis XIV compelled the elector by the treaty of Saint Germain-en-Laye to restore to Sweden all her German possessions except a district beyond the Oder, and by the treaty of Fontainebleau Christian V engaged to restore all his conquests to Sweden. Peace was concluded on these terms between Sweden and Denmark at London, 26 Sept. 1679.

Sweden, whose financial resources were always limited, had, however, been impoverished by the war, and the nobility, who during the minority of Charles had acquired the chief power in the state, although the king had assumed the government in 1672, became unpopular. A revolution was accomplished in 1690, in which the states, under the guardianship of a military force, declared Charles absolute and irresponsible, and entitled to dispose of the government as his last will. The remaining years of Charles XI were employed in organizing the army and restoring the finances. He adopted a regular system of conscription, which greatly strengthened the military power of the nation. He died 15 April 1697. His son, Charles XII, born in 1682, was declared of age in November. His youth induced Denmark, Poland and Russia to enter into a league against him to partition his dominions. Embarking for Copenhagen in 1700, he soon disinherited the plans of the allies, and refusing peace began a career of conquest, which after many marvellous successes ended in the disastrous battle of Pultava, 7 July 1709. After an exile in Turkey he returned to Sweden in 1714, reconciled himself with Peter the Great, and was pushing the conquest of Norway when he was killed at the siege of Fredrikshall, 30 Nov. 1718. The Swedish states passing over Charles Frederick, son of Charles' elder sister, named the second sister of Charles, Ulrica Eleonora, queen, who in 1720 associated with her husband Frederick I. The revolution was accomplished so suddenly that it led to a suspicion that Charles' death had been anticipated, and it has always been suspected that he fell by the hand of an assassin. The new government allied itself with Great Britain, and ceded the duchies of Bremen and Verden, the cause of quarrel between Charles and England, to George I. Peace was concluded with Poland on the basis of the treaty of Oliva, and with Prussia, to which Sweden ceded the territory between the Oder and the Memel, Stettin, the islands of Wolin, Bornholm, and Sweden. By the Treaty of Stockholm, 12 June 1720, Sweden paid Denmark 660,000 rix-dollars, and renounced the freedom of the Sound, while Denmark restored Kneen and other conquests in Pomerania and elsewhere. War still continued between Sweden and Russia. It was terminated by the Treaty of Nystad, 10 Sept. 1721. Sweden received 2,200,000 t. r. Livonia, but she finally lost the valuable Baltic provinces for which she had so long contended. Of her corsaria only restored Finland.

Sweden was now under the hands of garcy. This council was easily bribed by the German powers. It was called (after 1738) the Hats and Caps of which preferred to sell their France, the latter to Russia. On the out of the war of the Austrian Succession, Sweden, who had been irritated by the indignation of the Russian Empire of their ambassador to the Porte, was induced by France to declare war with the war on the part of Sweden, from incapacity and the selfishness of her ally was ill conducted. On the accession of the peace was concluded by the Abo, 17-18 Aug. 1743, by which Swumann forever her claim to the ceded by the Treaty of Nystadt, the part of which was the main ceded part of Finland, the boundary the two states being fixed at the river by the influence of Russia Adolphus of Holstein was elected successor to the crown, to which he succeeded on the death of Frederick I in 1731. During his reign Sweden took some part in the Seven Years War. At home the country was distracted by quarrels of the Hats and Caps, and power sank to a shadow. Adolphus 1771 and was succeeded by his son III. His reign was distinguished by chivalric revolution. He undertook a war against Russia, which brought him fame in the battle of Parnawa, was productive of no other result, and was assassinated in 1792. In 1809 Gustav IV was deposed, and his family future incapable of succeeding to the throne (The leading events of his reign will under Gustav IV). His uncle, the Sudermania, was declared king with the title of Charles XIII. He concluded a war with Russia, begun by Gustavus, by the Treaty of Tilsit, 17 Sept. 1809, by which Sweden rendered Finland, the Åland Islands at West Bothnia to Russia. In 1810 elected Jean Baptiste Bernadotte, crouned in the In the final struggle with Napoleon p 1814 Sweden joined the Allies, while the part of France. The Dano-Those driven out of Holstein by Bernadotte Treaty of Kiel was concluded between Denmark and Great Britain, 14 Jan. 1814 by this treaty ceded to Denmark German possessions in Pomerania, at of Rügen, while Denmark was ceded Norway to Sweden as a compensation for the loss of Finland. This was by the Norwegian Storting on 4th of 

Greenland, the Faroe Islands and which had belonged to Norway, were by Denmark. Sweden now held the whole of the Scandinavian Peninsula, and had in other European possessions. Bernadotte succeeded to the crown in 1818, under the name of Charles XIV. Under his reign Sweden advanced greatly in agricultural and prosperity. He died in 1844, and was by his son Charles, Louis Eugène, under t
V. Charles XV died 18 Sept. 1872, succeeded by his brother, Oscar II, on 8 Dec. 1907, was succeeded by the present king Gustav V. On 7 June 1940 to the refusal of Sweden to grant consulates to Norway, the Storting passed a resolution to dissolve the Reich was finally ratified by the Treaty ad by both countries on 16 October, over Prince Charles of Denmark the King of Norway.

9 Sweden experienced one of the most industrial strikes in the history of states. Beginning in a few industries, soon involved nearly 300,000 men for two months, completely paralyzed, commerce and transportation failed, and the defeat of the strikers.

in the World War.—The World which stimulated agricultural production in branches of mining, entailed great on the majority of the people, and development in the country became frequent, especially the urban districts. Up to the later the war the attitude of the Court (the was formerly Princess Victoria) of the military and official classes general of benevolent neutrality toward all Powers, while that of the Socialists, neutral, was more favorable to the The strict enforcement of the British by the seizure of contraband be sent through Sweden to German, detention of mails from the United aused intense irritation; and on the nd, the German submarine campaigns, sinking of Swedish ships, raised con feeling against Germany. Sweden's as a neutral was seriously comprom the revelations made by the United government in September 1917 that the Foreign Office was permitting German messages from foreign countries to be its own messages, these including mes om Count Luxemburg, German Chargés at Buenos Aires, in reference to the of ships of the Argentine Republic by es, the most extraordinary of which his government that Argentine vessels not be sunk at all, or sunk without any trace (spurios versendt). These as raised a storm of indignant protest allied countries, and a breach of dipollations between Germany and the Ar was narrowly avoided. SWEDISH LANGUAGE.—The North Germanic dialects seem to have differed very little from each other originally. A fairly uniform language was spoken all over the North which in English and Scandinavian sources is often referred to as "Donsk tunga." During the Viking age, between 700 and 1100, four dialects developed from the original Old Norse: Icelandic, Norwegian, Danish and Swedish. The former two are grouped together as Westnorse, the latter two as Eastnorse. Among the distinguishing features may be mentioned the passive ending -s for Eastnorse, where Norwegenian and Icelandic have -sk, f. i. kallas "to the called" versus kallas "to be called." The Old Swedish period extends to the time of the Reformation and covers geographically only not only Sweden proper, but also the coast districts of Finland and Livonia. Our knowledge of the earlier stage of Old Swedish is based on Runic inscriptions which only in the 13th century were replaced by the Latin alphabet. During the later Middle Ages many phonetic changes took place which tended to differentiate Swedish more and more from the other Scandinavian branches, such as lengthening of vowels, the Genitive ending -s instead of -r, the relative pronoun sum in place of aer, etc. The vocabulary absorbed many foreign elements, especially from Danish and German, as f. i. numerous industrial and commercial terms, all the verbs in -era (= German -ieren), the suffix -het (= -heit), the prefixes be-, bi-, un-. From this somewhat chaotic stage of transition which is characterized by absolute lack of linguistic norms or standards, modern Swedish emerges gradually as a literary language. The first complete Bible translation which is named after Gustavus I and appeared in 1541 is regarded as the first monument of modern Swedish literature. Throughout the 17th century grammarians and purists made efforts to create national standards and to eliminate foreign elements. In spite of that, however, a large number of French words crept into Swedish, especially in the 18th century and have maintained themselves to this day. The internal linguistic changes concern chiefly the simplification of case endings or inflections and the adoption of certain sound-shifts which are characteristic of modern Swedish, such as the s-sh sound for combinations like sj, stj, skj. The pronoun of address became ni instead of I. Since the middle of the 18th century Swedish grammar has changed very little, while the vocabulary shows quite a different appearance, particularly since the enormous wealth and variety of expression which is stored up in the dialects has been utilized by modern writers. The dialects of Dalarna and the island Gottland are especially noteworthy on account of their quaintness and archaic character.

Accent.—Longfellow who first introduced
SWEDISH LITERATURE

Swedish writers to the American public, characterizes the Swedish language as soft and musical with an accent like the Lowland Scotch. Jacob Grimm considered it even the most musical of all Germanic languages, comparable to Italian among the Romance languages. This musical character of Swedish is partly explained from the fact that it has retained full endings like -a and -o in many positions where the other Germanic languages have such sounds ended them entirely. More important, however, are the peculiar laws of pitch and modulation which hardly any other language has developed with such consistency. Certain combinations of stress and tone result in definite forms of a musical cadence of "tonlåg." The simple tonlåg, or acute accent, differs very little from that employed in other languages, the compound tonlåg occurs only in Norwegian and Swedish: the voice first sinks about two tones and rises suddenly two or three tones on the second syllable with a weak secondary stress. The question of accent and modulation is one of the chief difficulties in the study of Swedish.

German Department, University of Michigan.

SWEDISH LITERATURE. The intellectual life of the North has been at all times more or less dependent on central Europe, especially on German and French civilization. Swedish literature shows these influences in a marked degree and has only within the last generation produced writers of distinct originality and more than national significance. The mediæval period appears rather meagre as compared with those of Norway and Ireland, Codes of laws, chronicles, legends of saints, adaptations of chivalrous romances and didactic writings: these or similar categories cover a literary activity which is altogether imitative and chivalric of philological appearance. Among the historical documents may be mentioned the Erics-chronicle, covering the period from 1230-1320, the Nyh Chronicle (1400) and the so-called Small Kvhmechronique which contains some interesting autobiographies of Swedish kings. The most conspicuous religious character of the later Middle Ages was Saint Birgitta, who, after an extended experience as wife and mother, turned her mind to things spiritual, undertook reforms of all kinds, founded a religious order, came in touch with the leaders of heretical mysticism and was finally canonized in 1373 in Rome. She contributed to Swedish literature a volume of visions or "revelations" which in spite of their absurdness exhibit a remarkable power of imagination. Her personal influence and the activity of the Birgitta order which was centred in Vadstena, can be traced through the whole intellectual life of the North, especially in the direction of building up a national church and encouraging the use of the mother tongue. The ballad literature of the 14th and 15th centuries is not so extensive as that of Denmark or Germany, but corresponds otherwise in subject and form. Many of these lays and ballads wandered evidently from one country to the other and exist in numerous versions. More than 60 have been counted of the famous ballad "Elveskud" (translated by Herder as 'Erikings Daughters') which describes the dangerous lure of dancing elves. The Swedish ballads have been collected by Geijer and Aftelius as *Svenska folksvisor* (new edition by Bengtsson). Swedish thought and literature received a powerful stimulus from the gradual adoption of the Lutheran faith in the course of the 16th century. This movement is closely associated with the names of the brothers Petri, Olavvs and Laurentius, and of Laurentius Andreas. All three of them contributed to the translation of the Bible which appeared complete in Upsala in the year 1541 and which for the history of the literary language in Sweden may claim a similar position as Luther's translation for German. Apart from a rich controversial literature called forth by the religious movement, we meet with attempts in the dramatic field, such as treatment of biblical stories, allegories and school comedies. The most versatile writer of this period is Johan Messenius who, among other things, planned a systematic dramatization of subjects taken from Swedish history but who only completed six of such plays.

The heroic century of Modern Sweden, the age of Gustavus Adolphus and Charles XII, proved to be relatively unproductive in the field of literature. The dominant influence of Renaissance poetries throughout the 17th century discouraged spontaneous expansion and established in most European countries classicistic standards and a rule of formalism. Sweden reverses her "father of literature* in Georg Stjernhjelm (1598-1672), a stern disciplinarian who aimed at purity of language and formal interpretation. He wrote a number of epic and didactic poems of an allegorical character, among them his famous *Hercules at the Cross-road* and distinguished himself besides as a scholar and scientist in many fields. He introduced a number of classic and romantic metres into Swedish poetry and gained remarkable skill. His contemporary Gunnar Dahlstjerna employed even the Ottave rime (with six iambic feet) in his patriotic poem *Kunca-kald,* and is still appreciated as the author of *Gudina Kampevisa* in which Charles XII and Peter the Tzar are the leading
The greatest metrical genius of his

They seem more like free improvisa-
finished works of art, but it is this
ful freshness and bold impressionistic
manner which fascinates the modern reader as
much as their original audience.
The transition from the older 18th century
formalism to the Romantic age in Sweden
presents quite a dramatic spectacle. The first
writers who showed a more adventurous spirit
were Fanzen and Wallin, the latter still known
as the editor of the Swedish psalm-book and
as the author of a glowing ode addressed to
George Washington. After the revolution of
1809 the Swedish Academy ceased to be arbiter
of public taste, and soon the leading writers
of the Romantic movement in Germany were
eagerly studied and imitated. Two parties
formed and carried on a lively feud for a num-
ber of years: the Phosphorists, so called after
their periodical 'Phosphorus,' were more inter-
interested in the speculative elements of
German mysticism, as represented by Schelling or
Novalis, the Gothicists wished to strengthen
national ideals and to revive the old sagas
and ballads of the romantic Middle Ages.
The head of the first group was Peter Atterbom
(died in 1855), whose phosphorescent visions
recall somewhat the ethereal, transcendent
style of Shelley or Keats. Other members
were Nyberg, Dahlgren and Stagnellius, a
mystic and seer, reminding
us of the leading minds of the Gothicists were
Erik Geijer, equally great as poet and historian,
Per Ling who tried to revive the old saga style,
and his much greater follower Esaiah Tegner,
author of the Frithjofs Saga, Sweden's national
epic. Somewhat independent of either school
remained Karl Nicander who selected chiefly
Italian subjects and themes for his poetry, Chr.
Fahlcrantz, still quoted as a humorist, and
Johan L. Almqvit (1793-1866), an erratic
genius who combined exquisite delicacy of senti-
ment (as in his collection of lyrics: Törnrosens
hök) with an extravagant, even lawless
imagination and quite heterodox views on love
and marriage.
The chief by-product of the Romantic move-
ment, the historical novel, flourished in Sweden
perhaps even better than in England or
Germany. Gumalius, Crusenstolpe, Ridderstad,
Sparre and many others have contributed to
this genre. The Finlander Topelius so called
'Surgeon's Stories' which contain many
centuries of Swedish history, were widely read
in this country at one time, but slumber now
peacefully on the shelves of our libraries side
by side with Rydberg's famous novel 'The
Last Athenian,' and with Frederika Bremer's
once so popular stories and sketches of
Swedish home life. The last-named writer ap-
ppears already quite emancipated from Romantic
doctrines and points toward the coming age of
Realism. Swedish literature, as may have been
noticed, is immensely strong in the field of lyric
poetry, whereas the realistic novel of the
Dickens or Eliot type is rather poorly repre-
sented. Fr. Cederborgh, Karl Wetterberg,
August Blanche, Sofie von Knorring and a few
others present various aspects of Swedish life
and society in their novels. The realistic note
which had already been heard in the poems of
Anna Lenngren (died 1817), becomes more
and more prominent, and is reinforced by
humor and satire in the songs of W. von Braun,
Wennerberg, Sturzenbecker, and the witty
improvisations of Johan Wadsen. But all these
minor talents disappear by the side of the greatest poetic realist of his age: Johan L. Runeberg, the pride of Finland. His chief work is a collection of patriotic poems and ballads: 'The Finnish National Heroine,' which were inspired by the second Finnish War in 1809, and are rightly considered the most beautiful tribute that has ever been paid, to the patriotic enthusiasm of a small nation. The idyls 'Elk-hunters' and 'Hans' are the influence of Goethe's epic style and, with a large number of exquisite lyrics, give evidence of Runeberg's remarkable power to invest the simplest and most primitive aspects of life with genuine pathos and poetic dignity. He deserves to be classed in this respect with poets of the rank of Goethe or Wordsworth. Runeberg taught for many years in Borås, Finland, and died in 1877.

Two years after Runeberg's death, in 1879, there appeared a novel in Sweden under the title 'The Red Room' by August Strindberg, which inaugurated a new type of Realism and a new literary era. A few years later Geijerstam attempted in his first novel 'Erik Grane' to epitomize the great intellectual and social revolution which had gradually spread from one country to the other and was inspired by three constructive ideals: a political and social democracy, a reconciliation of science and religion, and a new aesthetic creed which substituted the truth for beauty. The compelling figure in this movement is August Strindberg, epomatching in all fields of literature and at all times a seeker of truth. Most of his writings are now accessible in English translations. Gustav af Geijerstam (1858–1909) who as a novelist has gained great popularity both in Sweden and Germany, is practically unknown to the American reader. This may be explained from the distinctly national or even provincial character of his art, partly from the peculiar inwardsness and savagery of his analysis which avoids striking plots or situations and instead delves down into the deeper strata and hidden recesses of soul life. However, such stories as 'Astray in Life,' 'Pastor Hallin,' or some of his short stories, are not only the theme of his later novels, like Erik Forsslund in 'Stockholm,' but are appealing more than some of Strindberg's rather morbid productions. Among the younger followers of the new realism may be mentioned Albert Engström, editor of the periodical 'Strix' and known through his descriptions of peasant life, sailors and fishermen. Two Swedish American novels may be added, one by Hilma Angered-Strandberg, called 'The New World' describing the struggle and failure of two people who have come to this country, the other by Henning Bergner, 'Isai' which contains a splendid description of Chicago as the great melting pot of races. The influence of Maupassant and Flaubert is noticeable in Hjalmar Söderberg's clever sketches of Stockholm society ('Historietten' and 'Blunders'), as well as in his novel 'Martin Birks Youth,' a story of disillusioned youth. Sigrid Siwertz, a short story writer, seems to develop in a similar direction, as, for instance, in his collection 'The New Robinson' (1887). In 1890 the pendulum seems to have swung back in the opposite direction of an idealistic or neoromantic interpretation of life.

Such is the literary creed of Selma L. the leading writer of the day, whose tales from Gösta Berling to the 'Poet of Portugallia' are being read in many. Her art certainly is the classic Waller definition of the romantic as 'strange to beauty.' Far less known is.

Heidenstam, author of the 'Karmac' series of tales grouped around the hero of Charles XII. This book has become a classic. Oscar Leverton died in 1883 may be regarded as the leading critic.
found in Vol. III and XVII of his de Skriften;" Runeberg is treated by in his "Northern Studies," London 1879.
and was severely wounded in the siege of Shiloh (1862 et seq.) and the årskatalog för bokhandeln.

where, after finishing his education, he preinticed to the printing business. He identified himself with the military com-

SWEENEY, William Montgomery, son of the foregoing: b. New York, 29 Aug. 1871. He was educated at public and private schools and academies in New York and Augusta, Ga. He has written for the press and contributed biographical articles to "Officers of the Army (Regular) who served in the Civil War" (Philadelphia 1892); "History of the Twelfth Regiment, N. G. N. Y." (New York 1894); "Journal of the American-Irish Historical Society" (Boston 1899); "White's National Cyclopædia of American Biography" (New York 1901) and Lamb's "Biographical Directory of the United States" (Boston). He is the author of the "Life and Services of Thomas William Sweeny, Brigadier-General, United States Army" (New York 1907) and editor of "Sweeney's Narrative of Army Service" (1846–53); "Captain Thomas Cook, a Soldier of the Revolution (1752–1841)" (New York 1909) and "Some Notices, Genealogical and Historical, of the Cook, Dandridge, Higgins, and Reagan, Reo and Sweeney Families" (in manuscript).

SWEET, Benjamin Jeffrey, American

military officer: b. Kirkland, N. Y. 24 April
SWEET — SWEET-GUM

1832; d. Washington, D. C., 1 Jan. 1874. In the Civil War he was colonel of the 21st Wisconsin. In 1863 he was placed in command of Camp Douglas, Chicago, where 10,000 Confederates were imprisoned and successfully circumvented the efforts of Confederate societies to seize Chicago and liberate their friends. He was made brigadier-general of volunteers in 1865 and in 1872 was appointed first deputy commissioner of internal revenue.

SWEET, Henry, English philologist: b. London, 1845; d. 30 April 1912. He was educated at King’s College, London, at Heidelberg University and at Balliol College, Oxford. He devoted himself to the study of phonetics and Old English philology and became one of the foremost authorities on both subjects. His researches into Chinese and Arabic were also of high value. From 1901 until his death he was University reader in phonetics at Oxford University. He edited numerous Old and Middle English works and was author of many papers on phonology and of 'A History of English Sounds' (2d ed., 1888); 'Primer of Phonetics' (1890; 3d ed., 1906); 'The History of English Phonetics' (1903).

SWEET, John Edson, American engineer: b. Pompey, N. Y., 21 Oct. 1832; d. 8 May 1916. He was educated in the district schools, became a carpenter’s apprentice and rose to be a builder and architect in 1850. He was employed in his profession in the South until 1861; engaged as an inventor and mechanical draftsman until 1873; from 1873-79 was professor of practical mechanics at Cornell. From 1888 he was president of the Straight Line Engine Company. He founded the American Society of Mechanical Engineers, of which he was president in 1883-84, and an honorary member. On his 80th birthday in 1912, he was given a banquet by the society. He was government expert and juror on machine tools at the World’s Columbian Exposition in 1893 and in 1899-1901 was first president of the Engine Builder’s Association of the United States. In 1904 he was given the John Fritz Medal, which is awarded by a board of 16 of the leading mechanical engineers of the United States and Electric Engineering Societies. In 1914 Syracuse University conferred upon him the degree of Doctor of Engineering.

SWEET-BAY, the classic laurel (Laurus nobilis), or bay-tree of the Mediterranean regions, which becomes a tree of some 50 feet in its native habitat, but is cultivated as a shrub farther north, being often trimmed like box. (See BAY.) It has handsome, lanceolate evergreen leaves, dark-green and shining, which have an aromatic odor and taste and are, therefore, employed in cookery and for pickling fish. They have also some therapeutic value and yield a thick oil which is incorporated into ointments and liniments. The sweet-bay of America is the small tree (Magnolia virginiana) called more frequently swamp-magnolia or swamp-laurel. See Magnolia.

SWEET-BRIER. See Eglantine.

SWEET-FERN, a low shrub (Comptonia peregrina), with many brown branches and long linear leaves, so deeply pinnatifid on either side of the midrib as to appear fern-like. The flowers are dioecious, without perianths, and appear when the leaves are fertile in globose amethysts follow-in 1 foot—rny nuts invested shaped persistent bracts. The fruits are longer and clustered at the ends of the peduncles. Young foliage is pubescent, and the plant has a strong aromatic fragrance bruised or under hot sunshine. It was included in the genus with the spicig—apple and is often found growing with it. Soils or on hillsides further inland. Leaves are sometimes used as a substitute for tobacco.

SWEET-FLAG. See Flag, SWEET.

SWEET GALE. See CANDLES.

SWEET-GRASS, a name given to plants, most of which are fragrant, especially drying. The small Anthoxanthum odorum of the sweet vernal grass and has narrow-like panicles of spreading one-flower clusters. The leaves are flat. This plant is introduced from Europe and is found in meadows over nearly the whole of the United States. It was given to the fragrance of the grass Stipa triciojorada is the vanilla-grass of Europe, which is strewed about churches and religious processions. Material from which the Indians of the Lawrence region weave their thin mats that, when made of the grass, retain their odor of new mown hay in Panicula is a genus of grasses for grass because cattle are said to be icious. Another sweet-grass (Apera rata) does not in the least resemble grazing whorls of leaves and white flowers in cymes. When dried it is however.

SWEET-GUM, a large American (Liquidambar styraciflua), reaching its size in the South Atlantic States, where it grows tall, strong and beautiful. It attains to 80 feet above the ground. The head is pyramidal when young, but when old grown the heads are likely to become rounded. The five-lobed, star-shaped perianth is form thick, dark brown, and is to the brilliant hues in autumn, the young especially being gorgeous in large star-like leaves, bright-green beneath. Tiliaceous flowers are inconspicuous and perennial. They are gathered into clusters of the pistillate ones being succeeded by globose and spiky with the points beaked woody capsules, which are twisted and allow the scanty fertile escape through gaping orifices. They are long stalks far into the winter. To very rough, and in young branches is peculiarly winged by numerous ridges of undulating outline, which suggested the name of alligator-wood. It is smooth and satiny and would beeast as a substitute for black walnut, were liable to warp and difficult to season. With a rinosus sap, which is used in a liquid like that of Liquidambar orientals in Asia, might be a source of gum stor migratory sap to seasonal parts under the the same name. The sweet otherwise known as star-leaved gum, or bilateral, red gum or opal.
SWEET MARJORAM. See MARJORAM.

SWEET PEA, an annual herb (Lathyrus odoratus) of the family Fabaceae. It is supposed
natively of Ceylon, Sicily and Sardinia, the original pink-and-white and the red varieties
being credited to the first country and the pure white and purple varieties to the other two
islands. The known history of the plant begins in 1650, and the first record of its cultivation in
1699, when Father Francisca Cupani grew it
at Panormus, Sicily. By 1730 the seed was com-
mercially known, and about 60 years later five
varieties were offered by a London seedsman.
Until Henry Eckford commenced experimenting in
1876 for the production of new varieties there
were, however, rarely 12 varieties offered in
any one year. Largely due to his efforts the
list of varieties had risen to 150 in 1885, and
the popularity of the flower had vastly extended.
It has been estimated that since 1900 the aver-
age annual crop of sweet-pea seed is about
100,000 pounds, about one-fifth of which is pro-
tected by patents. The nearly all the seed used in Europe and America is now grown.

The sweet pea is a hardy annual herbaceous
vine with rough, winged stems, tendril-bearing leaves composed of two lateral leaflets borne on long
stalks, and fragrant papilionaceous flowers of
various shades, ranging from white to blue and
red through many tints, and including both double and *hooded* forms. The pods are
about two inches long, and contain about six
known seeds. The double varieties are regarded with favor, being rather unkempt and
lacking theaintiness of the single sorts.

For best results in the garden, sweet peas
should be planted very early in the spring or
even during the previous late autumn. They
will thus obtain an early start, and their roots
will penetrate more deeply into the cool, moist
soil before warm weather arrives, than if sown
later. Moderately rich soil of a rather heavy
nature generally gives the best results; very rich
soil tends to grow vine and leaf at the expense
of flower; very poor ground is prone to produce
small short-lived vines and little flowers which,
however, are often pronouncedly fragrant. The
seeds should be scattered thinly in trenches
about five inches deep and four or more inches
broad. The distance between rows should be
about three and one-half feet, the seed covered
about one inch deep, and as the plants grow the
earth should be drawn toward the vines until it
forms a ridge two or three inches high. When
the plants are well above the surface they
should be provided with supports upon which to
climb. Brush and poultry netting are generally
employed. Throughout the season clean,
shallow cultivation should be given and the
flowers gathered daily. This last will consider-
ably extend the season since the formation of
seed tends to a cessation of growth.

Several closely related species are cultivated
for ornamental purposes but are less popular
than the sweet pea. The following are
notably the following: The Tangier scarlet pea (Lathy-
rus tangistanus), an annual herb which blossoms
earlier than the sweet pea and should be planted
separately because of its greater strength and its
tendency to crowd out the other varieties. The
perennial or everlasting pea (L. latifolius), an
dolorless species with many-flowered clusters of
diversely colored blossoms. It is popular for
planting among rocks, in rough places and for
screens, for which its rampant growth and hardi-
ness recommend it. L. rotundifolius and L.
grandiflorus are also called everlasting peas and
are cultivated to some extent, as are also L. mari-
timus, the sea or seaside pea, and L. palustris,
the marsh or wing-stemmed pea—the latter
grown in damp places.

Consult Hutchin,'All About Sweet Peas'
(1894), and 'Sweet Peas Up to Date' (Philadel-
phia 1897); Bulletins 111 and 127, Cornell
Agricultural Experiment Station (Ithaca 1895,
1896); Bailey, 'Standard Cyclopedia of Horti-
culture' (New York 1916).

SWEET PEPPERBUSH. See CLETHRA.

SWEET POTATO, a tuberous-rooted perennial herbaceous vine (Ipomea batatas)
of the family Convolvulaceae. The plant is of un-
known origin but is supposed to be a native of
tropical America. It has roundish or angular
heart-shaped leaves, and in cultivation rarely
produces blossoms, where the flowers resemble
those of morning-glory, but are smaller. The
tubers, which are borne below the crown of
the plant, are without well-defined eyes. The
plant was cultivated by the natives before the
landing of Columbus. It is now extensively
grown in many warm and mild climates, es-
pecially in the Southern States, California and
the Atlantic Coast as far north as New Jersey.
The annual crop aggregates about 50,000,000
bushels, and the yield per acre varies usually
between 200 and 400 bushels, though with best
management and favorable season 800 bushels
or even more are occasionally obtained.

The sweet potato is propagated less by its
tubers planted in the field than by sprouts ob-
tained from the tubers in hothods, etc. These
sprouts or 'draws' are transplanted in the field
as soon as the weather has become settled and
after the land has been deeply and finely pre-
bred by plowing and harrowing. The soil best
suited to the beets is a light sandy loam, but
excessively rich in nitrogenous plant food but
not deficient in this respect. Upon heavy soils
the tubers are prone to crack because of the
uneven growth under varying conditions of
moisture and dryness. Plenty of moisture, warm situation and liberal manuring are essen-
tial. The ground is kept cleanly cultivated until
the vines interfere with tillage. The tubers are
dug in the autumn and stored in a great variety
of ways, all considered more or less unsatisfac-
tory since the tubers usually decay badly during
storage. While the plentiful yield may fre-
quently beg a market in the autumn, the demand
from mid-winter onward can rarely be supplied
even at advanced figures. These troubles may
be considerably reduced by proper care in har-
esting. The following practices are recom-
mended: Digging before the tubers start a
'second growth,' choosing clear weather when
the soil is dry, using padded baskets to reduce chance of scratching the tubers, handling so as
to avoid bruising; the sprouts of the crop are
shorn and giving perfect ventilation in the stor-
age heaps which should always be located upon
knolls or otherwise dry ground. As adjuncts to
these practices the beds in which the sprouts
are obtained usually are provided with fresh
manure and the plants should never be set two years in succession in the same
field; three or four years is considered much better. These are all preventive and are thought to be more valuable than special methods of storage in expensive storage quarters.

Consult Georgia Experiment Station Bulletin No. 25 and Farmers' Bulletin No. 26 of United States Department of Agriculture.

SWEET-SOP, the edible fruit of an evergreen shrub (Annona squamosa). It is ovate in shape, with a delicious sweet pulp, enclosed by a thick rind having projecting scales. Although indigenous to America this tree is cultivated for its fruits in all tropical climates, and is also called sweet-apple, or, in India, custard apple—a name which properly belongs to A. reticulata.

SWEET SULTAN, a plant. See Cen- 
taurea.

SWEET WATERS OF ASIA, a river, the ancient Aretas, flowing between Anadoli Hissar and Kandili, on the Asiatic side of the Bosphorus. The Turks call it Ghiok-suyu, "the water from the serpent," from the surpassing beauty of its surroundings. The valley is a favorite picnic resort in summer and autumn, when the better class Turkish families may be seen on Fridays (Mohammedan Sabbath) in their private canoes (boats) on the stream or scattered along the shores using luxuriant cypress, sycamore and plane trees.

SWEET WINES. See Wine and Wine Making.

SWELL-FISH. See Globefish; Diodon.

SWENSSON, Carl Aaron, American Lutheran theologian: b. Sugar Grove, Pa., 25 June 1857; d. Los Angeles, Cal., 16 Feb. 1904. He was graduated from Augustana College, Rock Island, in 1877, and in theology from Augustana Seminary in 1879; was secretary to the General Council of the Lutheran Church of North America in 1885 and its president, 1893-94. He was a member of the Kansas legislature in 1889; founded Bethany College in 1881 and was its president from 1889 till his death. He was the author of hymn books and books of travel in Swedish and English.

SWETE, swêt, Henry Barclay, English theologian: b. Bristol, 14 March 1835; d. May 1917. He was educated at King's College, London, and Gonville and Caius College, Cambridge, where he gained several prizes, and was graduated in 1858. He was professor of pastoral theology in King's College, London, from 1882 till 1890, and examining chaplain to the bishop of Saint Albans from 1881 till 1890; and after 1880 was Regius professor of divinity at Cambridge. He was made honorary chaplain to the king in 1911. His published works include 'Early History of the Doctrine of the Holy Spirit' (1873); 'History of the Doctrine of the Holy Spirit in the Prince of the Apostles' (1876); 'Commentary of Theodore of Mopsuestia on the Minor Epistles of Saint Paul' (1880-82); 'The Old Testament in Greek,' according to the Septuagint (1887-94); 'The Ahimma Fragment of the Apocalypse (1890-91); 'The Apostles' Creed in Relation to Primitive Christianity' (1891); 'Faith in Relation to Creed, Thought and Life' (1895); 'Church Service and Service-books before the Reformation' (1896); 'The Gospel According to Saint Mark, and the Greek Text' (1890); 'Notes and Indices' (1891); 'Introduction to the Old Testament' (1900); 'Patriotic Study' (1902); and in the Teaching of Our Lord' (1903) of the Ascended Christ' (1911); 'Spirit in the Ancient Church' (1912); Last Discourses of Christ' (1913); 'The Holy Catholic Church.' He also contributed articles to Wace's 'Dictionary of Christian (Vol. III and IV, 1882-87); and to 'Dictionary of the Bible' (Vol. II 1890-1900).

SWIFT, Gustavus Franklin, merchant: b. Sandwich, Mass., 24 June Chicago, Ill., 30 March 1903. At the he opened a small butcher shop in h town, but removed to Boston when he was 30 years old. He returned to Boston 1875 when he went to Chicago, where he developed the department of shipping to eastern markets. In 1877 he evolved the first refrigerator car, and dressed instead of live animals, which had a great effect on the cities. He was the pioneer in this business from the small plant started in the 1870s. He developed the great corporation bearing his name.

SWIFT, Jonathan, English cl prelate, political writer and satirist: b. Ireland, 30 Nov. 1667; d. Dublin, 19 (30 Apr.) 1745. Swift was the posthumous son of Richard Swift, the neer-do-weel of a prosperous family which had a number of descendants. His father was a famous member of Swift's house. Thomas Swift (b. 1595), the famous vicar of Goodrich. Through Thomas marriage to Elizabeth Dryden, great great-grandfather of Swift's relation to Swift's mother, Abigail Erick, of Leics was a distant cousin of Sir William 1 a woman of much character and wit. Swift's life divides itself into three periods: to the death of his mother, in 1699; from that year, to the age of 80; and the rest of his life in Dublin, where he almost continuously lived. The story is that he was taken at the one year from Dublin to Whitby, by his nurse, where he lived two years, to read in the interval. At the age of he entered Kilkenny School at the time of his uncle, Godwin Swift. Entering Trinity Dublin, in April 1662, he was graduated years later without distinction, and in 1665 was publicly censured for his studies and for tavern-haunting. His diet was probably much more than his studies and was friendless. His de on the charity of his relatives was his pride, and he was a happy, but the consequences were not very serious. Swift Ireland in the fall of 1688 by the real Tyrconnell, and he and his mother retired to Ireland, where in 1690, he became to Temple at Moor Park, near Londe.
position was a somewhat menial one, but his patron's kindness enabled him to take the degree of A.M. at Oxford in 1692. Returning to Temple but finding his position irritating, he refused the latter's offer to obtain for him a clerkship in the Irish Rolls, quarreled with his employer and entered the church. Ordained deacon in October 1694, and priest in January of the following year, he obtained the living at Kilroot, Ireland. Tiring of his position, however, he applied to Temple for reinstatement, and the latter, glad of his help, called him back to a post of greater importance, early in 1696. Here Swift remained till his patron's death in January three years later.

The decade ending with that date is very important to the life of Swift. Intellectually, he was very active and, besides his routine duties, did a prodigious amount of reading. Though he did not always understand his motives accurately, he was nevertheless not far from the truth when he described his temperament in a letter to a friend who had cautioned him to beware of ambition: "He was about to make. Protesting that he could have no thought of matrimony until his position in the world was secure, and adding that he was very hard to please, he continued: "How all that suits with my behaviour to the woman in hand you may easily imagine, when you know that there is something in me which must be employed, and when I am alone turns all, for want of practice, into speculation and thought; insomuch, that these seven weeks I have been here, I have writ and burnt, and writ again upon all manner of subjects, more perhaps than any man in England. And this it is which a person of great honour in Ireland (who was pleased to stoop so low as to look into my mind) used to tell me that my mind was like a conjured spirit that would do mischief if I did not give it employment." (To Rev. John Kendall, 11 Feb. 1691). Whatever may have been the exact truth of the matter, Swift's constitutional restlessness was aggravated by a malformation in the region of the ear, which resulting in blood pressure, caused the attacks of giddiness and deafness to which he was always subject and which drove him to intense activity for relief (consult Craik, Appendix, XIII, and Collin p. 237).

His first writings, however, were of no importance. Falling under the influence of Cowley, he produced his first extant poem in May 1699, a very stilted Pindaric Ode to Dr. William Sanrcoft, and the seven known poems, chiefly odes, which he wrote before 1698 are of no better quality; it was the fourth, 'To the Athenian Society' (1691) that, according to Johnson, caused Dryden's damaging remark, 'Cousin Swift, you will never be a poet.' His vein then suddenly changed, and in 'Lines written in a Lady's Ivory Table-Book' (1698) and 'Mrs. Francis Harris's Petition' (1700) he first displayed evidences of the graphic, humorous description and the complete absence of sublimity which distinguish his work.

Far more striking are the two works which opened his career as a prose writer. Among a probably large amount of writing now lost, he composed, in 1696, 'The Battle of the Books' and 'A Tale of a Tub,' both of which remained unpublished until 1704. The year 1696 may be taken as the date when Swift abandoned his efforts to imitate the writings of his patron, and leaped, full-armed, into his own peculiar and inimitable possession, satire. 'The Battle of the Books,' the one piece now read in a once famous controversy, in which Temple had engaged, as to the relative merit of the Ancients and the Moderns, is famous for its satire, affectation, pedantry and obtuseness and for its lively burlesque of the heroic manner. The other book, a much more elaborate affair, by many regarded as Swift's masterpiece, is in its narrative parts a satire against religious abuses and schism, in the persons of Peter, the Church of Rome, Martin, the Anglican Church, and Jack, the Presbyterian sect. This narrative, however, comprises no more than a third of the book; the remainder is taken up with digressions, prefaces and digressions, which variously satirize the vanity, conventionality and affectation of authors, the irreverence and surliness of the wits of the day, the pedantry, the cheapness and superficiality of contemporary learning, and, in greater fear than hope, vanity and emptiness. In these two books, written before he was 30, Swift showed himself to be an unrivaled master of irony, burlesque and satire.

In the summer of 1699 Swift became secretary and chaplain to Lord Berkeley, one of the lord justices of Ireland. Disappointed in his efforts to obtain the deanship of Derry, he was made in February 1700 vicar of Laracor, Agher and Rathbeggan, in County Meath, Ireland, livings worth about £200 a year. On the resile of Berkeley in 1701, he went with the latter to London and published his first political pamphlet, 'The Dissensions in Athens and in Rome,' an attempt to show the need of harmony in politics. Though the pamphlet gained the goodwill of the Whigs, Swift's work for the next nine years was wholly in behalf of the Irish clergy. Four journeys to London, of an average duration of over six months apiece, were undertaken chiefly with a view to obtaining remission of the taxes on the Irish livings, and during the same period Swift wrote a number of able pamphlets in support of the established church, of which the masterly piece of irony, 'An Argument to Prove that the Abolishing of Christianity in England may, as this is understood, be attended with some inconvenience, and perhaps not produce those many good effects proposed thereby' (1708), and 'The Sentiments of a Church of England Man, with respect to Religion and Government' (1708), are the most important. During these visits also, Swift came to know the best wits of the time, the chief literary result of which were the famous 'Bickerstaff Pamphlets' (1709-10), a practical satire against false learning in the person of the astrologer Partridge. His principal purpose, however, came to nothing; he was put off by the Whig lords, and, personally disappointed because of his failure, owing perhaps to the impression created by 'A Tale of a Tub,' to gain preferment in the Church, he gave his services to the Tory ministry which came into power in 1710.

During the next four years Swift wrote an extraordinary number of political pamphlets; few political writers have ever done a larger amount of brilliant and powerful work. Swift's
task was threefold: to show that the cause of the Tory ministry, its desire to obtain a peace with France, was a just cause, and that its members were worthy men; to cast ridicule on the pretensions and perfidies of Whig; and to restrain the more violent Tories from extreme measures. His first work, after a caustic "Short Character of Thomas, Earl of Wharton" (1710), was the conduct of the Examiner, the organ of the Tory party, which he had between 2 Nov. 1710 and 14 June 1711, contributing a series of varied and able arguments and satires. His position, maintained with singular adroitness, was that the country was crying for a peace and happiness which could be more readily obtained from the Tories than from the Whigs, especially while Marlborough and Wharton were influential. In "The Conduct of the Allies and of the Late Ministry in Beginning and Carrying on the Present War" (November 1711), commonly regarded as his masterpiece among the writings in support of the Harley administration, his object was to strip the war of its glamour and to render it unpopular by showing that the Allies, the constituent parties of the Whigs, had been systematically exploiting England. After ten years of war with perpetual successes, he says in his preface, "to tell us that it is impossible to have a good peace is truly mioptrical—and it is natural to inquire into our present condition; how long we shall be able to go on at this rate; what the consequences may be on the present and future ages; and whether a peace, without that impracticable point which some people do so much insist on, he really ruinous in itself, or equally so with the continuance of the war." Other important tracts were "The Importance of the Guardian Considered" (1713), a merciless, but not unprompted attack on Steele, and the savage and fairer answer to Steele's "Crisis," the very skillful "The Publick Spirit of the Whigs." Besides his political writing, Swift published many pieces of a miscellaneous kind, including several papers for Steele's Tatler, at least one for the Spectator, some controversial satires on religious subjects, his historically interesting but philologically unsound "Proposal for Correcting, Improving, and Ascertaining the English Tongue" (1712), and the well-known "Journal." He became acquainted with the acquaintance of Esther Johnson, then a child of eight, during his first residence at Sir William Temple's, and had been the tutor to this ward of his patron. When he got his livings in 1700, she, with her companion, Mrs. Dingley, went to Ireland to live near him, and during his residence in England remained in Ireland. The "Journal" extends from 2 Sept. 1710 to 6 June 1713, with scarcely a break. The letters, which were dispatched every two or three weeks with an entry of the events of the day, were the personal and character of a busy and influential man of the time.

As a reward for his great political services, Swift was appointed, on 23 April 1713, dean of Saint Patrick's Cathedral, Dublin, and the following year to Ireland, at the charge of his new office. Returning to London in August of the same year with a view to healing the growing breach between the Tory ministers, Oxford and Bolingbroke, he was unsuccessful and returned to Letcombe, Berkshire. On the fall of Oxford and the triumph of Bolingbroke, Swift wrote "The Progress of Praise" (1713), and saw the close of his political career in England. On the death of Queen Anne, 1 Aug. 1714, the downfall of Bolingbroke and the complete triumph of the Whig party, he returned at once to Dublin, where he remained continuously for the next 12 years.

In Ireland he found himself very unpopular, and in his Church had trouble with his chapter and the archbishop, King. For the next six years he lived quietly, busying himself with his duties and writing only a few pieces, chiefly short letters of advice, articles on manners, etc. In 1716 he may have married Stella. The evidence is conclusive neither way, but the probability is against the marriage. At all events, she continued to live near him till her death in 1728, an event which caused him profound sorrow. Of the various, and occasionally heated, discussions that have arisen about this famous love story, the conclusion of Sir Leslie Stephen to the effect that the question is not practically important in determining the character and achievement of Swift. In 1720 Swift again became active. For the next 18 or 20 years, until he would no longer, his very voluminous production has three main aspects: that in behalf of the oppressed people in Ireland, both clergy and laity, that for the doctrines and the establishment of the Anglican Church; and the miscellaneous humorous and satirical writing, both in prose and verse, on which his popular literary fame largely rests. Beginning with a "Proposal for the Universal Use of Irish Manufactures" (1720), he followed his usual tracts on other subjects, and in 1724 began his most celebrated piece of polemic writing, "The Drapier's Letters." These very powerful, effective, but not wholly fair pamphlets were occasioned by a patent which had been issued to one William Wood to coin 100,000 of copper or silver coins in Ireland. Swift, in the first three letters, addressed the people of Ireland, under various classes, and with much skill in the selection of arguments suitable to each class, advising them to shun the coinage which the English government was trying to foist upon the Irish public. Then, having prepared his ground, he launched forth, in the next three letters, against the general right of the English to exploit and oppress the Irish. He closed the series with a letter, not published till 1735, "An Humble Address to both Houses of Parliament," in which he powerfully reviewed the woes of Ireland and made proposals for remedying them. The letters caused great excitement: the printer was arrested and a new trial of the law for the apprehension of the writer; but they produced their effect and the coinage was refused. Swift became very popular, and his position enabled him to pursue the subject of his last letter in many other acts. The unstable condition of Ireland is the burden of his political song, in such able pieces as "A Short View of Ireland" (1727), and "Maxims Controlled in Ireland" (1728).

The most remarkable of these public pieces is the very extraordinary and able "A Modest Proposal for Preventing the Children of Poor People in Ire-
Swift, in his maturity, is represented in the several extant portraits of which those by Charles Jervas are the most interesting, as a man of large frame and handsome countenance. Contemporary accounts represent him as a man of much distinction of manner and powerful presence, and above all as intellectually among the greatest of his time, and his influence was uncommonly great. From the time of the 'Draper's Letters' he exercised a remarkable sway over the affections of the
SWIFT.—SWIFT CREEK

Irish, and is said to have been the most popular man in Ireland. By his friends he was greatly beloved and the charm which his personality has exercised on most of his biographers has frequently made them protagonists and led them to minimize some evident defects of his. Each in his mercilessness to his opponents and his not infrequent coarseness, defects which he shared with many of the ablest men of his time.

Among all the able writers of the age he is surpassed by none in range and power and by none, except Defoe, in voluminosity. His known writings comprise over 230 separate prose titles, varying in length from the 'Meditations on a Broomstick' to 'Gulliver's Travels,' upward of 300 poems and some 500 letters. Within the limits of his style, which may be defined as the simple, intense and unadorned, as opposed to the ornate or the sublime, he is complete master of his medium and his sureness of touch in the large number of varied subjects that he treated, give him a place among the greatest of his era. Neither philosophical intricacy nor emotional appeal interested him, but as master of simple, racy English, of irony, humor, burlesque, satire and invective, he is unsurpassed, as he is also in his management of the topics with which he deals. Though he is remembered in literature chiefly for his great satires, nearly all the titles cited in the foregoing columns are models of their kind in writing. See Battle of the Books: Gulliver's Travels; Tale of a Tub; and Bibliography.—The best editions of Swift's complete writings are still those of Sir Walter Scott in 1814 and 1824 (2d ed.) in 19 vols. The most convenient and accurate modern edition of the prose is by Mr. Temple Scott (begun 1898) in 12 vols. of the Bohn Library. Other editions and selections of his prose and verse are too numerous to mention specifically. The principal early biographies are Orrery's 'Remarks on the Life and Writings of Swift' (1752), Delany's 'Observations' (1754), Dean Swift's 'Life of Jonathan Swift, the Life, Writings, and Character of Dr. Jonathan Swift' (1755), Hawkesworth's 'Memoirs' (1755), Johnson's in the 'Lives of the Poets' (1780), Thomas Sheridan's 'Life' (1784), Monck-Berkeley's 'Enquiries into the Life of Swift' (1791), John Barrett's 'An Essay on the Earlier Part of the Life of Swift' (1898), Sir Walter Scott's 'Memoirs' (prefixed to the edition of the works), all of which tell much the same story. Scott's is the best. Monck Mason's 'History and Antiquities of Saint Patrick's Cathedral' (1810) contains much interesting and valuable matter. The more modern and authoritative lives begin with John Forster's 'The Life of Jonathan Swift, 1667-1711' (1875), unfortunately unfinished. The most complete and accurate life is, on the whole, that by Sir Henry Craik (London 1882). Sir Leslie Stephen's in 'The English Men of Letters' is also good. Other lives are the enthusiastic study by J. Churton Collins (1893), the less interesting 'Dean Swift and His Writings' by Anthony Munday (1893) and the introduction to the British Edition by W. F. H. Leckey. Consult also Smith, S. S., 'Dean Swift' (New York 1910); 'Correspondence,' edited by F. F. Bell (ib. 1914) and 'The Bibliography of the Writings of Jonathan Swift' (in 'Prose Works,' Vol. XII, New York 1908); Historical Review (March 1918).

IPT-MOTHS, a cosmopolitan family "tidae) of large or medium-sized moths, erized by brownish or golden wings, ex-

IPTS, birds of the family Micropodidae "sleep"), noted for the extreme rapidity

of the place in the system

ology has been much discussed. For-

were universally classed with the s, but the usual opinion among ornithol-

I have a generally swallow-like aspect. l is very small, flat and weak, but the

which is not provided with bristles, extr

back beneath the eyes, giving a very eopen. Just at its base above are the partially covered by feathers. The feet small without any distinct scaly cover-

they present

ible peculiarities in the position of the d and the number of phalanges in the dif-
genera. The wings are extremely long, r far beyond the tail and crossing, but h lies entirely in the extremely clon-

quills, the upper segments of the d the secondary quills being unusually In the typical swifts the tail is long and in others it is short, truncate and there are always 12 retices. Amongal characters swifts have the salivary markedly developed and of the mucous e lower intestine has no ceca; the skull stigpoid processes in those which e palate of the passerine (agithognath-

pe has been combined with the ate (shizognathous) type; the keel of nium is remarkably deep and the pectoral correspondingly well developed. Ex-

they shun the polar regions these insectivorous birds are cosmopolitan in trition. There are about eight genera species divided into the subfamilies of dau-

spine-tailed swifts. The first has the hers normal, the tarsi and toes feath-

hind toe capable of being turned later-

ally or forward and the three front toes with only three joints each. Nearly all of the species of this group belong to the Old World, several being South American, and one belonging to the United States. In C. niger and C. ater, the feathers are directed forward. To this genus belongs the common swift of Europe (C. apus) and the Alpine swift (C. alpinus). The only representative of this group occurring within the United States is the white-throated rock swift (Aëronautes melanoleucus), found in the southwestern region north to Wyoming and in winter in Mexico and Central America. The hind toe is directed laterally, not forward, and the toes are only partially feathered. The colors are black above with some white mark-

ings and white below; the length about seven inches and the closed wing the same. This species is gregarious and nests in extensive colonies in holes and on ledges of inaccessible cliffs. Like the European swift its flight is incredibly rapid. Among other similar true swifts, none are of greater interest than palm swifts (Tachornis) of Africa and the tropical Orient and the aberrant tree swifts (Macrop-
teryx) of India and Ceylon, which nest in trees.

The subfamily Chatsurinae has the feet more normal, but the hind toe is more or less versa-
tile and the phalanges of the front toes, though not reduced in number, are extremely short; the feet are unfeathered and the tail feathers have the vane wanting at the end, the produced shaft forming a stiff mucronate tip. The common chimney swift (or erroneously swallow) (Chatsura pelagica) is an example, and is too well known to require a description. It is a migratory species and one of the very latest birds to appear in summer. It breeds as far north as Labrador and winters southward to southern Mexico. Its western limit is the cen-

tral plains. This is one of the birds which has been reputed to hibernate at the bottom of ponds and not a few circumstantial accounts of the manner in which they entered the mud have been published. Several patient, truth-loving, zoologists have carefully investigated these reports with the expected result that they proved baseless. The nests of this swift are interesting structures of twigs glued together under a thick coating of hard varnish-like dried saliva, which also serves to attach the saucer-like struc-
ture to the inside of an unused chimney, which at the present time are the almost exclusive nesting and sleeping sites of these birds. Formerly they occupied hollow trees and still do in unsettled parts of the country. The eggs are pure white and number four or five. Most of the life of these birds is spent in flight, and many and remarkable are their aerial perfor-
mances. The only other swifts of this sub-

family inhabiting the United States are Chatsura vanuvi of the Pacific States, there replacing the eastern chimney swift, and the black swift (Cypseloides niger) of the Rocky Mountain region and westward from British Columbia to Central America. It ascends to great altitudes. Several species of the latter genus occur in South America. Callioptia includes the edible birds'nest swifts (q.v.) of which a number of species occur in southeastern Asia to Madagascar and the Marquesas. Consult, besides the articles referred to above, and the standard works on American
Ornithology, especially Hartert, 'Catalogue
Birds British Museum' (Vol. XVI, London
1892) and 'Cambridge Natural History' (Vol.
IX, New York 1907).

SWIMMING, the art or practice of loco-
motion or mode of progression in the water
by using the arms and legs as paddles. Ac-
cording to the best authorities, all animals, ex-
cepting man, monkeys and, perhaps, the three-
toed sloth (Bradypus Tridactylus), either swim
naturally or go through the motions of swim-
ing when suddenly immersed in water. There
are, however, a number of animals that, al-
though they swim naturally, drown as they
swim. This is the case with rabbits, mice,
moles and the smaller cats. Drowning appears
to be the result of the fur being saturated.
Tigers, cheetahs and lions, the larger cats, are
fine swimmers. It is noteworthy that the mole
and the rat are equally strong swimmers, the
former, however, drowns in a short time, while
the latter has considerable endurance in the
water and is credited with many feats of long-
distance swimming.

The conditions under which an animal will
swim well are those in which the wetted sur-
faces are large, the more so, the greater the
power of resistance, and where the specific
gravity of the object is a little greater than
that of water and consequently subject to the
least disadvantageous displacement. Almost
all of the larger quadrupeds, especially the deer
and the horse, are exceptionally fine swimmers.
They simply walk in the water, the motions
which serve to support and propel them in
that medium being very similar to those em-
ployed to progress on land.

On the other hand, in the swimming of man,
it is necessary to consider a semi-artificial
mode of progression, which is, however, sub-
ject to and regulated by the general laws gov-
erning aquatic locomotion in relation to the
medium, the body immersed therein and to
the forces exerted by that body to propel itself.
The human body with a normal amount of air
in the lungs is very slightly lighter than water
and the movements of the limbs produce various
effects, according to the direction of the effort.
When the limbs are carried horizontally and down-
ward they tend to support and propel the
body. When they are moved in an upward
direction, as in diving, the body is given a
tendency to descend. As to the immersed sur-
faces, their direction tends to either float or
sink the body. When a man wishes to float
in the water he assumes a flat position resem-
bning the natural position of the lower swim-
ing forms and for purposes of propulsion and
support employs the "dog paddle," in which the
motions of the hands are exactly similar to
those of the forepaws of a dog in swimming or
in walking; a method of swimming em-
ployed naturally by almost all land animals.

In many men's initial efforts to swim re-
sult in positions of the body and motions of
the limbs which closely approximate to those of
the lower animals that swim naturally, he has
adopted and developed artificial methods by
the use of which he surpasses them in speed
and endurance.

These methods involve motions of the limbs
which may be conveniently designated as the
breast or front stroke, the side stroke, the
overhand stroke, swimming on the back,
floating and treading. In general, so
the arms and legs move in any direct
forces exerted tend to propel the b

![Fig. 1.—Breast Stroke.](image)

The breast stroke consists of a brush
of the arms in a horizontal plane, ac-
bored by a frog-like motion of the legs. It
is effected by placing the hands with
upward, the wrists being bent sideways
the fingers point to the front and
sides of the wrist joints touching
about four inches below the surface
water. The arms are then pushed geo-
ward, the palms being kept flat and the
fingers pointing to the front and
sides of the wrist joints touching
about four inches below the surface
water. The arms are then pushed geo-
ward, the palms being kept flat and the

the deeper immersion of the head reduces its weight and relieves, somewhat, the strain of its support from the muscles of the neck. If on the right side the right arm is thrown out in front with the palm of the hand turned downward and kept level with the under side of the head. It is then pushed out to its full extent, kept rigid and without bending either the wrist or the elbow, is brought down through the water in a strong movement until the hand at full stretch comes between the legs. It is then brought up along the body to the chin and the stroke repeated. The left hand, formed into a scoop, is turned outward by the wrist at right angles to the forearm and the left arm, with elbow bent, is thrown outward and executes a straight pulling stroke to the left hip. The arms act alternately and when one is executing the positive, the other is at the negative part of the stroke. The action of the legs should be long and powerful and coincident with that of the arms and shoulders. When the right arm finishes its downward stroke and the left arm is extended in front, the legs are drawn up to the body. When the left arm pulls downward, the legs are opened wide, swung around and closed, in one continuous motion. Care is taken never to cross the legs, make any effort to raise or sink the head, or exert any sudden pull at any part whatever of the complete stroke.

In the overhand stroke, all the movements excepting those of the upper hand and arm, are similar to those of the side stroke. The left or upper arm is brought forward and extended as far as possible out of the water in front of the head, then dipped and pulled through with a strong propelling stroke. The method gives a more lengthened reach and when properly acquired, is the most useful and easy of all the various methods of swimming; but the side stroke is the one generally employed in long-distance racing.

One of the fastest strokes for short-distance swimming is the Trudgeon stroke, introduced into England a few years ago from the South Pacific. The action of the arms consists of alternate overhand strokes, while the legs made a frog kick simultaneously with one of the arm strokes, with the body swimming on the belly. A modification of this style was introduced a few years ago by Meffert, the American mile champion, and has been adopted by some of the best American swimmers. In it the head and the forearm are kept submerged when the body is being pushed forward and the face is brought out of the water to breathe, by a turning action of the waist as the forward movement checks between the strokes. This style prevents a cramped position of the head and also allows a freer action of the body. Many racing swimmers take a breath only every other stroke, keeping the face half under water half of the time.

Swimming on the back is accomplished by lying in the water back downward, the hands resting on the waist, the elbows directed outward, the breath held and the chest expanded. To propel, the legs are bent and the feet are drawn up close to the trunk, the knees being directed outward with the heels close together. The legs are now struck out as wide apart as possible and then brought closely together until the great toes, inner ankles and the inner sides of both legs meet along their entire length. Greater speed may be obtained by extending the arms outward and on a level with the
body, the palms facing downward and using them as sculls. Diving, when well performed, is a very graceful feat. The dive may be a standing or a running one. To make a good dive, the feet line and legs are kept close together, the chest inflated and the arms are swung back and forth two or three times. The lungs are then charged with a long, deep breath, and the dive is made just a moment before the arms and hands are raised over the head. In springing off, all the power of the legs is used, and in mid-air the body is straightened out like an arrow from the tips of the fingers to the toes. The arms are then declined so as to enclose the head, the chest is contracted for an instant and the water is entered noiselessly and without a splash, fingers first. The moment the body is covered, the head and arms are thrown up, which brings the diver to the surface. The eyes, which instinctively close as they enter the water, should be opened under the water, in order to avoid accidents.

Floating is the position assumed by a swimmer to rest. It is accomplished by holding the forehead below and the mouth and chin above the surface of the water. The arms and legs may be stretched out as far apart as possible, as in the spread eagle position or the body may be held rigid and straight with the legs crossed, the lower part of the face and the toes peeping above the water and the arms either lying at the sides or above the head with the thumbs locked.

Treading water is a method employed to maintain a perpendicular position in the water, the head being kept above the surface. It is accomplished by paddling with the hands and working the legs and feet as if going up stairs, with the soles of the feet acting as sustaining surfaces. It is the only branch of the art that approaches natural conditions and if resorted to in cases of accidental immersion, would prevent 75 per cent of the deaths due to that cause.

Expert swimmers are capable of dispensing with the use of the arms, and when treading for display, or in competitions, either hold their arms and hands above the surface or fold them across the chest. They are also capable of floating with both legs or both arms out of the water, spinning like a top while maintaining a sitting position; taking off the clothes on the body; taking off the stockings and cutting the toe nails, all of which illustrate man’s command over the attending artificial conditions.

Aids to increase speed may be employed in the form of wooden plates which are attached to the palms of the hands and the soles of the feet. The most effective are those invented by R. H. Wallace Dunlop and introduced in England in 1876. Other helps, for sustaining purposes, have been employed from very early times. They were generally in the form of flat surfaces of wood, tin and water-proof fabrics, but their use is not recommended.

The Amateur Athletic Union of the United States holds championship swimming competitions in various places every year. The Hawaiian Association has a very large following and holds numerous contests. There are also intercollegiate, metropolitan and many local competitions.

A general idea of the speed and endurance of swimmers may be obtained from a few of the best performances on record: 100 yards—P. McGillivray (American amateur), 54s. (in bath); D. P. Kah’oku (American amateur), 53s. (in open water); A. Wickham (Australian professional), 1m. 4s. (in open water).

One mile—D. Billington (English professional) 24m. 11½s. (in open water); B. Kieren (Australian amateur), 23m. 16½s. (in bath); G. R. Hodgson (Canadian amateur), 23m. 34½s. (in open water). Woman’s record—Fannie Durack (Australian), 26m. 8s.

Long-distance swimming—Webb, 40 miles with tide, 9h. 57m. 00s.; Mercadier, 20 miles with current, 4h. 59m. 46s.; Miss Agnes Beckwith, 20 miles with current, 6h. 25m. 00s.

Long immersions—Webb, 20 miles, increased to 35 miles by tides, crossing the English Channel, 21h. 45m. 00s.

SWIMMING BLADDER, AIR-BLADDER, or SOUND, an internal sac-like organ in fishes by which they regulate their relative buoyancy. See Fish.

SWINBURNE, Algernon Charles, English poet: b. London, 5 April 1837; d. 10 April 1909. He was the son of Admiral Charles Henry Swinburne, of an old Northumbrian
and Jane Henrietta, a daughter of the 1 of Ashburnham, a woman of high who exercised a marked influence on the actual development of the poet during his early years. From Balliol e, Oxford, where his time was chiefly devoted to the study of Greek poetry and in less of the literatures of France and Italy. ofte, also, for the Undergraduate Papers, edited for him, and he was among the first to give a considerable body of verse which, however later characterized as worthless. He xford in 1860 without taking a degree, for a short time on the Con visiting Walter Savage Landor in 1861, for whom he entertained a great ad-

The year of his leaving Oxford was 1858, on the publication of 'The Queen of Sheba,' and 'Rosamond,' which, written in iambic tetrameter, revealed little metric and aroused practically no attention. In winburne settled in London, in the house of Rossetti. In 1865 appeared his first volume of verse, 'Atan Calydon,' which was hailed as giving evidence of his being the best writer of the time. 'Atalanta,' six volumes of verse of which he had earlier attained, does not go. These works are 'Centuries of Roundels,' 'Stanzas,' 'Lonicera,' a tragedy (1885); 'Lonicera,' a tragedy (1887); 'Poems and Ballads,' a selection (1889); 'The Sisters,' 'Lodore,' 'The Tale of the Brothers,' and 'Rosamond, Queen of the Lombards,' which were Balen's, of these Balen perhaps ranks nearest to the great works of his earlier period.

Swinburne also wrote much prose, in the field of criticism, possessing many of the characteristics of his verse, vehemence, imagery and lack of self-restraint. Although he possessed the gift of the illuminative phrase and displays at times a profound insight, his criticism as a rule shows no refinement of judgment. It was his avowed conception of the mission of criticism not to weigh narrowly and to examine minutely, but generously to praise. But though Swinburne was so far unique to his position in his regard as a poet, as well as loved, he hated and loved with unrestrained passion. He wrote eulogies on 'Charlotte Brontë' (1877), 'Shakespeare' (1880); 'Victor Hugo' (1886), and 'Ben Jonson' (1889). To Robert Buchanan's assault on the 'Fleshy School of Poetry,' including Swin burne, Rossetti and Morris, the first replied in his scathing 'Under the Microscope.' Among his other works of criticism are 'Essays and Studies' (1875); 'Miscellanies' (1886), and 'Studies in Prose and Poetry' (1884) and his position should also be made of 'The Modern Heptalogy,' a volume of parodies on contemporary poets, which appeared anonymously in 1881 and has not been, as yet, officially acknowledged as a work of Swinburne. His it was, however, by common consent and that in spite of the fact that among the most amusing burlesques is the one on himself. Swinburne's position in English literature is to be assigned him on his merits as a master of verse form and poetic rhetoric. With no essential profundity of thought, with no definite theory of life, with no deep insight into human character, he stood pre-eminent as a molder of
exquisite melodies. It is his manner that should give him a permanently high rank among English poets. (See ATALANTA IN CALYDON. Consult Wateslaw, Theodore, 'Algernon Charles Swinburne, a Study' (London 1900); Sheeherd, R. 'Chimneys of Swinburne' (1887); Mackail, J. W., 'Swinburne' (Oxford 1909); Thomas, Edward, 'Swinburne' (New York 1912); Drinkwater, John, 'Swinburne: An Estimate' (ib. 1913); Woodberry, G. E., 'Swinburne' (ib. 1905).

SWINDON, England, in Wilts., 29 miles northeast of Bath and 76 miles west of London, consists of two parts — old and new Swindon. The older section on a hill is picturesque and its principal buildings comprise the parish church, town-hall, assembly rooms and corn exchange. The new town on reclaimed lowland contains a mechanics' institute, theatre, etc., the railroad shops of the Great Western Railway employing several thousand men and an extensive park connected with these works. The town is an important railway junction. Pop. 50,751.

SWINE. General Information.—Swine are of immense importance in the commerce of the world. In the United States alone there are some 65,000,000 of swine on the farms and in the hamlets. This figure some two-thirds of a hog for every human being in this nation.

Swine products are many and various, fats, particularly lard, is one of the chief production. A real fat hog produced on corn in the pastures of the corn belt may yield as much as 50 pounds of fat in every hundred pounds of his live weight; hams which are eaten fresh, boiled, fried, cured with hickory and other smokes, are relished the world over; bacon, the toothsome breakfast dish of Anglo-Saxons, has no substitute; sausages; spare ribs; pepsin extracted from pigs' stomachs for the medicinal doctoring of human stomachs; the bristly coat is used for brushes and as filler for cushions; the bones are ground for fertilizer; the hide is made into leather; in truth every ounce is utilized, nothing goes to waste.

The source of the hog is shrouded in considerable mystery, although the true swine, the wild boar and his kind (Sus scrofa), probably domesticated continent. Fossil remains have been found in Europe and India although not on the North American continent. The Pecaries found in Mexico and other southern countries are not to be confused with the true domesticated hog that is of such great commercial value. The Pecary is of American origin. The historic swine, therefore, that gave rise to the present common hog may be basically considered as the wild boar (Sus scrofa) with which was infused in the early days the swine of China, Japan and eastern Asia (Sus Indicus). An eminent Chinese scholar estimates that swine were domesticated in eastern Asia about 2000 B.C., whereas the European records indicate a period of domestication about 1500 B.C. To these early efforts of the human race we owe much for the improvement and development of the now-a-day swine.

The flesh of swine has been used by all peoples, apparently who came in contact with them. The Chinese, as we know, were adepts of the fine art of preparing and serving pork.

Pork is of particular advantage to civil peoples in that it can be preserved by salting and other forms of curing so that may be kept in edible condition for many years. Hams rightly cured appeal more to the epicure as the years unfold, so that five and six years from the "culling" are particularly appetizing. In the ordinary consumption of pork, however, hams seldom remain a first birthday before being eaten.

And smoked meats from the pig are enjoyed by the world and many a nation considerable of its prosperity to its commerce.

Types and Breeds.—The do is to an entirely different from his wild Forcious and species to the advantage. We have, therefore, two different types, one the so-called bacon and the other the lard hog. Naturally the bacon hog is fine for bacon, and the lard hog is primarily of American lard hog. The former is developed simultaneously with Indian corn as a feed for the swine. The flesh of the pig's metabolism into the lard and the belt pork sausages. Denmark, England and Canada are all good bacon type regions. Denmark principally because of her milk products and England because of her excellent pastures and cereals and Canada because of her cereal grains and milk products.

Contrast the original wild hog with every-day American lard hog. The wild hog is narrow, more like one's hand viewed from the front, but the lard hog is wide in the rear. In fact, in the contrast; the former is relatively small in comparison. In short, the lard hog is not only wider and larger, but longer, better \( n \) shorter nosed, shorter \( c \) longer, more muscular, more \( f \) in body, shorter tusked and not nearly so ferocious and spirited and of less use as an animal. Too, the lardhog has a better quality of meat and a higher proportion of the most highly valued cuts of meat in proportion to the total weight, this being marked in the development of the lard hog and lard hogs, the result of the selected and persistent selection of these animals for breeding purposes that most nearly approached the desired type. This has been possible in the years of endeavor to develop such a contrasting type. The development of this lard type is more remarkable in that the very characteristics which make up this type are supposedly inimical to the best health and bodily interests of the hog. Too much fat decreases vigor and vitality, and we are not surprised to find that the hogs which are large, robust, and vigorous, because they are not unduly fattened in truth the general selection in this bacon pro-
1. The Iowa Community Sunlit Hog House. Here is a new kind of hog house—one substantially but economically built for swine. It is a sanitary, economical and serviceable house of pleasing appearance.

2. The system of feeding is responsible for the difference in size—the large shote had all the corn he wanted on alfalfa pasture, and the little one only one-fourth of a full ration. It pays to feed swine liberally.

3. The self-feeder method of feeding grains is efficient.

4. The Iowa Movable Sunlit Hog House, well lighted, sanitary, convenient, economical, serviceable and durable.
1. Land type — the Chester White — a white breed

2. A lean type — the Poland China — Note black color and white mantle

3. A lean type — Yorkshire Gilt — a pure white breed
ducing business has been to develop muscular tissue, the chief emphasis being placed on its proper distribution with some, not too much fat, to make the most acceptable slab of bacon and the nicest *trimmest* hams, hams that do not require *too much trimming away of the fat*.

The typical bacon breeds are Tamworths and Yorkshires. The Berkshires may be so classed because they yield the highest quality of bacon, but the Berkshire is sometimes placed in the general purpose class, good for bacon and good for lard. Then there is the Large Black of England.

The typical lard type breeds are Poland China, Chester White, Duroc Jersey, Victoria, Cheshire, Essex and Suffolk.

The general purpose breeds may be classed as the Berkshire, Hampshire, Mule-Foot and possibly the Middle White.

The score card method of teaching judging is in vogue in all of our leading agricultural colleges. A number of points make up the total, or the ideal, and the relative emphasis to place on the different parts is indicated by the number of points as given for perfect. Below are given representative score card values as used by the Iowa State College at Ames, covering the bacon and lard types in the barrows. The relative descriptions show where the emphasis is placed in each type.

There are a great many swine terms that need defining. A few of the important ones used in swine husbandry are given:

**Swine:** General name for any or all of the domesticated, omnivorous, suid mammals supposedly descended from the *Sus scrofa* or *indicus*, or infusion of the two, more specifically known as Duroc Jerseis, Poland Chinas, Chester Whites, Berkshires, etc., Hampshires, Tamworths, Yorkshires and other established breeds with their various cross-bred and mongrel breedings. Untamed wild animals are referred to preferably as &quot;Wild swine.&quot;

**Hog:** May be used synonymously with the term &quot;Swine&quot; but refers preferably to marketable animals.

**Gilt:** Young, immature, prospective swine mother.

**Sow:** Female swine after producing young.

**Boar:** Well-developed male swine suitable for breeding service.

**Boar Pig:** Young male swine under breeding age, usually under six months old.

**Stag:** Swine castrated (*"desexed"*) after the noticeable development of the secondary sexual characters such as tusks, shields, enlarged sheath, crest and others. Stags are docked 70 pounds on the large markets.

**Barrow:** Swine castrated before the sexual characters develop to a noticeable extent.

**Pig:** May be used synonymously with swine but preferably in America refers to those under three months of age. In England, Canada and Australia, pigs are swine of any age or weight.
Shote: Immature swine of either sex, except boar pigs, usually weighing from 60 to 175 pounds.

Weanling Pigs: Young pigs after weaning time.

Suckling Pigs: Young pigs following their mother and yet unweaned.

Pork: The dressed meat of swine used for food.

Management and Handling.—In the housing of swine to be paid to these essentials: Warmth, they do not thrive in real cold and freezing quarters; dryness, if kept in damp quarters contract various ills such as rheumatism and stiffness; abundance of diffused light; much direct sunlight, appropriately so for the new-born offspring to give them strength and stamina; shade, especially in the very hot months; ventilation, to insure fresh pure air; sanitation, to prevent diseases; safety; comfort; convenience, this being true not only for the swine but for the caretaker.

Swine should not be compelled to unnecessarily exert themselves, unless it be at certain time when particular advantages are to be gained thereby for the herdsman: serviceability to shelter advantageously, durability; reasonably low first cost; minimum cost of maintenance; and pleasing appearance so as to harmonize with the general surroundings adding by all means to the artistic and architectural beauty of the community.

In the feeding, the ration must be well balanced else the swine will not thrive. Corn alone in dry lot, even though plenty of water be supplied, together with salt, is deficient, in that it does not supply all of the nutritional factors necessary for the growth and well being of the pig. To illustrate, well-nourished swine eight months of age can be made to weigh 300 pounds, but they must have a balanced ration to do this,—such as corn, maize and milk (skim, butter or whole); or corn and alfalfa or clover or rape pasture together with a little meat meal; or corn and meat meal, both being fed in separate open containers, same being kept filled with feed and before the swine at all times. Corn fed pigs at eight months old fed by the Iowa Experiment Station weighed 57 pounds, and yet the first three months of this feeding time the pigs had a good ration. Similar pigs fed on corn and meat meal from the packing houses weighed 225 pounds. The corn pigs required 1,447 pounds of corn for 100 pounds of gain, but the ones receiving meat meal in addition needed only 366 pounds of corn plus 48 pounds of meat meal, a total of only 414 pounds of concentrated feed. Less than a third as much feed was required where the properly balanced ration was fed. It is wise and proper to vary the ration, giving equitable feeds in the right proportions and thereby giving the pig a chance to develop properly. Both the art and the practice of swine feeding are learned only by much experience mellowed with keen insight into the psychology and the nutrition of interesting but oftentimes perplexing animals.

The costs of production that enter into the making of marketable hogs center around these import items: Feed, such as the grains; pasture; equipment covering houses, troughs, fences and other details; man labor; horse labor; interest on the capital invested, an annual miscellaneous, or overhead, expense give a comprehensive idea as to the distribution of the total cost, or 100 per cent, among the mentioned items:

- Feed grains grown and purchased
- Pasture to supplement grains, also lot rent
- Man labor
- Interest on the investment or capital
- Horse labor
- Equipment upkeep
- Overhead expense

**Grand total expense**

The Swine Commission of the United Food Administration in the year 1917 that it took the equivalent value of 12 hogs to produce one hundred pounds of pork, which is market the average hundred pounds of marketable hog delivered to the Chicago, the general market hog market of the world. This counts the costs of all teritory and only keeps of the herd. Defend therefore, this means that if number two hogs is worth a dollar a bushel of that the farmer who ships to the mark the cost not on the average make any money. He gets over $12 a hundred pounds for the hogs. The good farmer will of course put them more cheaply, but when the costs put down to the 12 bushel basis that is good indeed. Of course the man who bungles the garbage, the kitchen waste from the city towns, can produce hogs more cheaply than the man who feeds high-priced grains. He can start his pigs from six to nine pounds of garbage to produce as much pork as a pound of mixes agent grains.

The best forage crops and pastures for are alfalfa, red clover, dwarf essex rape, grass, rye, wheat, soy beans, cow peas, sweet clover. All of the clovers are esp. good.

The best grains are Indian corn, barley, wheat, sorghum seed, kaifir corn, milo oats, peanuts, soy beans, cow peas, and oats similar nature.

The best balancers of the ordinary are the milks, meat meal, packing house age, linseed oil meal, wheat middlings, corn meal, blood meal, peanut meal, bean meal, gluten feed, together with the preferably leguminous and tender pastures.

To secure the greatest success in the feeding and management and marketing of swine must look to these essentials:

First.—Locate the business where the hogs are favorable to pork production usually being where there is an abundant cheap grains and other feeds suitable for and where the markets are relatively good and easily accessible. Go to those sections hogs are making their owners money.

Second.—Select good, sound, healthy, foundation stock of the right market as the right right hogs type.

Third.—Have an ideal and work toward in your feeding and breeding operations.

Fourth.—Feed a properly balanced
one that will supply the essential nutrients at the right time.

Fifth.—House the animals in sanitary, well-lighted, comfortable convenient quarters.

Sixth.—Keep the animals healthy by sensible methods, use preventive measures to avoid cholera, the scourge of swine husbandry, this being done by immunization, using the anti-hog cholera serum perfected by the government, and purchaseable most everywhere.

Seventh.—Be a good manager, keeping everything and everybody lined up so that the whole scheme harmoniously works to a common ideal of doing the right thing, in the right way, at the right time. There are many corners to watch, as in all good businesses, hence the vigilant watchful spirit is to be as industriously cultivated.

Eighth.—To be most successful in the swine business one must like it, put his heart into it, yes, and live with it.

JOHN M. EVARD,
Professor of Animal Husbandry, Iowa State College.

SWINTON, William. American educator: b. Salton, Scotland, 23 April 1833; d. New York, 25 Oct. 1892. He came to Canada in 1843, where he studied at Toronto and then to the United States, where he continued his studies at Amherst College. He subsequently taught at Greensboro N. C., and in New York and during the Civil War was war correspondent of the New York Times. From 1869 to 1872 he was professor of English language and literature in the University of California. His writings include: 'Rambles Among Words'; 'Twelve Decisive Battles of the War'; 'Campaigns of the Army of the Potomac'; 'Word Analysis'; 'Studies in English literature,' and 'Outlines of the World's History.'

SWISS FAMILY ROBINSON, The, a famous romance by J. R. Wyss, which was begun by his father and published as 'Der Schweizerische Robinson.' It was translated into French and afterward into English. It is an entertaining tale written for young people, after the style of 'Robinson Crusoe,' from which the author is supposed to have derived many of his ideas, and has been cleverly parodied by Owen Wister in 'The New Swiss Family Robinson' (1882).

SWISS GUARDS. Swiss companies served in France from the time of Louis XI, who paid particular attention to cultivate the friendship of the cantons. In 1571 Charles IX created the charge of Colonel-General of the Swiss at Montmorency, who commanded all the Swiss in the kingdom, except the 100 guards of the king. The institution of the Swiss guards as a complete regiment dates from 1616. In 1714 it was composed of 12 companies, some of which had two captains. Louis XIV gave it five officers to each company. All the officers and men were Swiss, and the companies mounted guard before the king according to the rank of the cantons to which their captains belonged. The Swiss guards followed in order of precedence after the French guards. They enjoyed liberty of worship. According to the arrangement with the Cantons, the Swiss guards could not be obliged to serve against Germany beyond the Rhine, against Italy beyond the Alps, or against Spain beyond the
Pyrenees. This convention was often broken. The attachment of the Swiss guards to the king made them obnoxious to the people during the Revolution. They were repeatedly banished and recalled, and on and after 10 Aug. 1792, when they were delivered to the mob against the mob, they were massacred without mercy. The Lion of Lucerne was designed by Thorwaldsen in memory of their heroism. At the Restoration, a Swiss Guard was formed to guard the person of the worthless Bourbon, but it was dispersed by the Revolution of 1830. The Vatican Palace, Rome, the residence of the popes, is guarded by a company of Swiss, who are termed the Swiss Guard. Consult Stephens, H. M. 'History of the French Revolution' (2 vols., New York 1891) and Ternaux, 'Histoire de la Terreur' (8 vols., Paris 1863-81).

**SWISS LAKE DWELLINGS.** See Lake Dwellings.

**SWISSHELM.** Jane Grey, American reformer and author: b. Pittsburgh, Pa., 6 Sept. 1815; d. Swissdale, Pa., 22 July 1884. She was an ardent abolitionist; an ardently ardent advocate of negro rights; an angry, hot-blooded, burning opponent of slavery; and while editing the Saint Cloud (Minn.) Visitor had her office and press destroyed by a mob for advocating abolitionism. She was among the first to become a nurse in the Union army. Besides voluminous contributions to current periodicals, she published 'Letters to Country Girls' (1853), and an autobiography 'Half a Century' (1881).

**SWITCH GRASS.** See Grasses in the United States.

**SWITCHBACK.** An inclined railway in which the progress of the train or car on the descending route is effected partly or wholly by gravity, the car first running down a steep incline and by its momentum surmounting a lesser incline, alternate ascents and descents continuing to the end of the course. Switchback railways are constructed also by curving a track alternately backward and forward along the side of a hill thus obtaining practicable grades for descent. The switchback method is popularized in the circular switchback railways, a common feature of American resorts. The Mauch Chunk Switchback in Pennsylvania is one of the best known of these gravity railways. It was formally used to carry the coal from the anthracite mines to the valley; the coal is now transported through a tunnel, and the switchback is reserved for the amusement of visitors. See Railways, ELEVATED.

**SWITCHBOARD.** See Electrical Terms.

**SWITCHMEN'S UNION OF NORTH AMERICA.** See Railway Labor Organizations, Railroad Organizations.

**SWITHIN, or WITHERUN, Saint.** Bishop of Winchester (died 832). He was tutor to King Egbert's son Ethelfluid, a zealous builder of churches, and of conspicuous devotion. He is credited with many miracles and when he died asked to be buried where "passers-by might tread on his grave and where the rain from the caves might fall upon it." When a century later his body was to be exhumed for the purpose of being deposited in the Cathedral, on the day appointed for the translation (15 July) it rained a full 40 days after so as to delay the ceremony, it was believed, originated the popular belief that if it rain on Saint Swithin's day wet weather 40 days after it.

**SWITZERLAND.** Fr. La Suisse; Ger. Die Schweiz; L. Ital. Il Sottc. An ancient federal republic of Central Europe, extending between 45° 49' 2" and 47° 30' 26" N. latitude and 5° 7' 26" and 10° 29' longitude. The superficial area is 15,983 square miles; greatest breadth, 226 miles; greatest breadth, 136 miles. The country is a confederation of 19 whole cantons, the whole divided into ministrative districts. It is bounded north by Baden, with the Rhine as its northeastern boundary; Bavaria and Württemberg to the northeast; Switzerland to the southeast by Liechtenstein and the Tyrol. The Rhine and the Grison Alps intervene between it and Geneva, natural boundaries, and the area is northwestern by France, where the Alps and the Rhine form natural boundaries; and the valley of the Rhine and the River Doubs form the demarcation. The following table shows the cantons, their areas and population, areas in which they joined the confederate

Nearly all the cantons have all names in French and German. Thus, in Luzern in German, while Obwalden are known as walden-le-Haut and Unterwalden-le-Inférieur. Zug has a French equivalent Solothurn in Solothurn; Grischaubünden in German; Neuchâtel in Neuchâtel; Ticino, Tessin; Vaud and Waadt, and Wallis, and Geneva, Genf.

**Topography.** Embracing the highest mountainous land in the Central Alps, Switzerland has been aptly styled the Switzerland of Europe. Its frontiers are mainly composed of mountains, rivers as

Those great mountain ranges and the
of easily-blocked tunnels by which it is possible for troops to cross them; said to make the country absolutely impenetrable in the hands of a determined garri-son. During the European War, Switzerland was a solid rock in the midst of a turbulent sea of nations at war on all the four fronts. That "fortress" was the strategic point of the mid-European battle-ground; its rear would have had an enormous military value for any one of the belligerent nations. These lofty ranges there are gigantic, magnificent lakes and wild, romantic.

Though Switzerland contains the ranges of the Alps and the greater part of the Jura chain, the highest peaks of the Alps belong to France. Physically the Jura falls into four natural divisions, the Alps, the Outer Alps (Voralpen), the Bernese Oberland, and the Bernese Oberland, and the Rhone valley. Other passes connect Switzerland with Italy; the most important being that of the Great St. Bernard in the Pennine Chain, that of the Simplon in the Lepontine Alps, the Saint Gotthard (q.v.) at the head of the valleys of Reuss and Ticino, and those of the Bernina, Splügen, of the Grisons southward. Altogether about 40 commercial highways pierce the Alps, besides a larger number of natural passes unprovided with roads. Of the great pass-roads connecting Italy through Switzerland with southern Germany the most important in Roman times and in the Middle Ages was the Septimer Pass (7,580 feet), connecting the head of the Val Bregaglia with the Rhine valley above Chur by way of the Oberthal and the Rhone. The Saint Gotthard was not known to the Romans, but was frequented by pilgrims in the 13th century. The Simplon pass (6,600 feet) was a paved Roman road; the railway tunnel which runs under it was opened in 1906. The Great Saint Bernard pass (8,110 feet) connecting Switzerland with Italy starts on the Swiss side at Martigny in the valley of the Durance, and ends at Aosta in the Dora Baltea valley.

The famous hospice of Saint Bernard is mentioned in documents of the 10th century. The avalanches of Switzerland are famous for their destructive propensity, but on their record, year by year, they do not cause any appalling loss of life or property. The mighty forces of nature, in storms at sea, inundations and cyclones, cause probably a much greater proportionate loss of life and property than do avalanches. Though they fall all the year round in Switzerland, spring is the great time for avalanches. During that period some of them descend with remarkable regularity in particular places and at recognized spots. The snow piled up during the winter on the grass slopes below the (summer) snow-line, gradually loses its cohesion as the spring melting advances and glides down to its appointed place according to the trend of the ground. In places where huge masses of snow are collected above steep declivities terminating in narrow outlets the avalanches descend with terrific roar and pressure against the lines of defence — the forests. For this reason the forest laws of Switzerland are very strict. Everything is done to preserve the natural rampart afforded by a mass of pines, and no one is allowed to fell a tree on his own ground with government consent. Where avalanches fall regularly every year, stone galleries are built or tunnels are mined out of the solid rock to protect roads. Many protective devices are em-ployed to arrest the torrents of ice, snow and slush so that the danger from them has largely diminished. The Co-operative or Dust-Snow avalanche is the most dangerous on account of its suddenness, and the most difficult to provide against. This is a collection of loose, freshly-fallen snow which has been caught up in one of those sectional tornadoes that spring up on the mountain slopes, and is
driven down on the wings of the wind to the valley below. The Schlag-Lawine or Stroke-Avalanche is the usual spring variety, which pours down the slopes like a swiftly-flowing river. This is the type that can be more successfully regulated. It has a secondary form in the Grand-Lawine or ground avalanche, which carries earth and rubbish with it and performs a beneficial task in bringing down soil from the heights to the plains. Whereas the avalanche is snow in quick movement toward the valleys, the glacier is snow (pressed into ice) in slow movement. See Glacial Period; Glacier.

Rivers and Lakes.—Owing to its mountainous nature Switzerland is naturally a land belonging to many river systems, though none of the rivers acquires such a size within its limits as to become of much navigable importance. Its position as the centre of the principal watersheds of Europe has been referred to. Great rivers take their origin in Switzerland and their main stream of development in other countries. Both the Rhine and the Rhone rise here, as well as the Po and the Danube. The first three spring from the Saint Gotthard mountain mass, but the Rhine is formed by the junction of three distinct head-streams, the Vorder, Mittel and Hinter-Rhine. It flows north into the Lake of Constance, and thence west to Schaffhausen, where it forms the celebrated falls of that name, the largest in Europe in volume. It is navigable for vessels at Core in the canton of Grisons, for vessels of 150 tons, but its navigation properly begins below the falls. Its principal affluent in Switzerland is the Aar, which, after traversing the Lakes of Brienz and Thun, winds across the Swiss plateau to join the main stream about midway between Lake Constance and Basel. The Rhone, said to be the most rapid of the larger rivers of the world, rises in the Rhone glacier (Valais), flows northwest in the Lake of Geneva, issues thence at the town of Geneva under the name of the Arve', and quits Swiss territory about 10 miles below. The waters which the Po receives from Switzerland are carried to it by the Ticino, and thereby to the eastern bay of the Mediterranean, just where the Danube receives are carried to it by the Inn and then thence to the Black Sea. The lakes and mountains form a more important hydrographical feature than the rivers. The former are remarkable for their number, size, depth and the grandeur of their scenery. The largest lake, that of Geneva (also known as Lake Leman), has an area of about 220 square miles; Lake Constance, in the northeast, has 208 square miles. Both of these, as well as Maggiore on the south side of the Alps, belong partly to other countries; but within the limits of Switzerland, and not far from its centre, are Lake Neuchâtel (93 square miles), with Morat and Bienna in its vicinity. Thun with its feeder Brienz, Lucerne or Vierwaldstättersee, Sempach, Baldegg, Zug, Zürich and Wallenstättere. All these internal lakes belong to the basin of the Rhone. The greatest depth of Lake Geneva is 1,015 feet, placing the bottom at about 200 feet above sealevel, the bottoms of the lakes on the southern side of the Alps are below the level of the sea. Rapid mountain torrents feed nearly all the Swiss lakes, entering their upper end charged with sediment, which is deposited on the lower end. Thus filter and regulate the rivers, thereby reducing to a low flow the lower valleys of the country, floods. The Aar flows from its banks, but this has been remedied by the construction of a canal to divert the lake of Bienna, by which the low tide of the stream is regulated.

GEOLOGY AND MINERALS.—The most notable feature in the complicated structure of Switzerland is the extent to which the Alp range has been folded, contorted and uplifted by the tremendous forces that have led to the formation of these mountains. A typical example is presented by the Saint Gothard, where the core of the range has been uplifted and the strata on each side of it have been forced up so that the slope is almost perpendicular. At the summit, the appearance of the ribs of a fan radiating from a single point. All the loftiest Alp peaks have a nucleus of granite, on which mica-slate reclines generally at a high altitude. On the north side, the Jura give way to the Jurassic rocks of which they consist; the mountains on the east are formed of gneiss and mica-schist with slates in places, especially in the Grisons. The slate rock is found in the North Germanic region, stretching from the northeast of the Geneva and the lakes, may be described as an area of principally Miocene deposits. This two mountain regions composed chiefly of more ancient date. Switzerland is known for its mineral springs. Thermal and mineral waters are dotted all over the country. Baden, the chief of the bath centres, enjoys the popular climate and its hot springs have been celebrated since Roman times. The health resorts are those of in Aargau, Pfeffers in Saint Gall, Louéche and Saxon in Valais, Saint-Blanien, Weissenburg and others of Berne; Weissbad near Appenzell, in Glarus, Seewen in Schwy. Andermatt in Unterwalden, and many others are on 400 health resorts in Switzerland, many containing luxurious Kurhäuser, hotels, clubs and other numerous attractions for devotees of sports and tennis lawns. Native initiatives have so successfully exploited the gifts of nature that Switzerland has been called the "playground of Europe."—if not of the world.

CLIMATE.—The climate of the Alps is characterized by the altitude and the easterly winds, which bring moisture in the form of snow to the southern side of the range. The known wind is the Föhn, a dry northeasterly wind that blows with great velocity.

are as high as 33° and 66°. Some
lying valleys, especially those that
the east and closed to the west, are
said to have nine months' winter and
the conditions.

Fauna.—The differences of elec-
ally the climate and the natural
is of the soil, hence few countries in
of larger extent, can boast of a
d vegetation than Switzerland. The
Alps is one of peculiar interest.
Alp ranges the Alps harbor
able number of plants found nowhere
of those which are found elsewhere
ity do not reappear in the plains and
ow, but in distant mountains on
ations. Out of upwards of 800
species to the Alps, but not to the adjoin-
s, nearly one-fourth are absolutely
these mountains, and nearly a fifth
also in the Arctic regions, these
are hence known as Arctic-Alpine
as the elevation ascends there is a
range in the aspect of the vegetation,
been divided into seven regions.
In
adjacent countries, Switzerland
in increasing the atmospheric moist-
the valleys at the base of the moun-
tains chestnut and walnut grow freely even
on the north side, while in the valleys
opening toward the Mediterranean lies a zone occupied
by these trees while still at a considerable elevation.
Higher up is the zone of the beech,
maple and other ordinary foliage trees reaching
about 4,000 feet, and then the zone of
fruits and pines rising above 4,000 feet higher.
This region is followed by one of Alpine
shrubs, among which rhododendron, (Alpine
roses), heaths and whortleberries are conspicuous,
along with larches and two species of pine,
the dwarf-pine and the cembra-pine, remarkable
for its edible seeds and peculiar to this zone.
The shrubs cease to grow at about
height of 7,000 feet, but the Alpine plants that
cover the pastures intermingled with the shrubs
ascend to the snow line, and even beyond in
places too steep for snow to lie. Heer collected
about 100 different species of flowering plants
above the snow limits on the Alps and lower regions
Grisons at about 8,500 feet; 24 species have been
observed on the Grisons Mules on Mont
Blanc at a height of from 9,800 to 10,600 feet;
and the sides of the Pizzo Centrale on the Saint
Gothard have been known in August to emit
for a considerable distance the fragrance of
the flowers which covered them in patches. The
celebrated edelweiss, which all Alpine tourists
celerately collect, is the most retiring of these
snow region plants. Of utility plants the
characteristic product of the plain and lower regions
is the vine, which grows up to about 1,800 feet
above sea-level. The hilly or lower mountain
region up to 4,000 feet produces good crops of
barley and oats and excellent pastures. Above
this, in the Sub-Alpine region, up to 5,500 feet,
no regular crops are grown; in the upper
Alpine region the vegetation becomes more
stunted and the variation of the seasons is lost.
Beyond lies perpetual snow. Many plants even
of the lower parts of the country are stony and
sterile, but no spot that can be turned to good
account is left unoccupied. Though chiefly an
agricultural country, Switzerland cannot grow
enough crops to support its population, so that
the majority of the foodstuffs have to be im-
ported. The productive land is divided among
some 300,000 peasant proprietors who raise,
besides the crops already mentioned, wheat, spelt,
rye, potatoes and tobacco, and manufacture
cheese, condensed milk and wine. Nearly 30
per cent of the entire area is unproductive and
about 30 per cent is under grass and meadows.
Considerable quantities of fruit are grown.
Among domestic animals the first place belongs
to the horned cattle. At the last census there
were in the country 130,613 horses, 1,615,645
cattle, 171,635 sheep, 850,000 pigs and 358,000
goats. In the summer the cattle are fed on
the numerous mountain pastures or 'alps,' but
of their winter fodder a large proportion has
to be imported. In several cantons bee-keeping
and silkworm culture are carried on.
Among the wild animals are bears, wolves,
chamois, goats, boars, stags, badgers, foxes,
hares, otters, squirrels; birds of prey of large
dimensions; the snipe, heathcock, cuckoo, black-
and woodpecker. The lakes and rivers
produce a varied abundance of fish.

People.—The Swiss are a mixed people as
to race and language. The bulk of the popula-
tion is of Teutonic race, but the Latin race
(partly French, partly Italian) compose nearly three-sevenths of the whole. The Swiss Teutons belong to the Alemannic stock and still speak a distinctive Alsatian dialect usually called the Swiss German or simply Swiss. They occupy the whole of the upper Rhine valley, as far as its extreme western angle at Basel, consequently the whole of the Helvetian highlands lying north of the Central Alps, besides the upper Rhone valley down to Sion or Sitten, under the Bernese Alps. The rest of the upper Rhone valley and the western slopes of the Jura are French, comprising the cantons of Valais, Vaud, Geneva, and Neuchâtel. The Italian portion is made up of those parts which belong to the basin of the Po—the whole of the canton of Ticino and the valley of Poschiavo in the Grisons. Along the head streams of the Rhine, in the valleys of the Grisons, and in the region between these rivers and the banks of the upper Inn, and even still farther eastwards, in some Tyrolean valleys beyond the Swiss frontier, are scattered the Rumonsh-speaking people, whose language at first sight seems like a dilemma of connecting link between German and Italian. These are the interesting Rhaeto-Romance tribes, which had long failed to receive the attention of the scientific world. Critical research has since established that Rumonsh is an entirely independent Neo-Latin tongue, standing on the same level as Spanish, Portuguese, Italian, Langue d’ Oc, Moldow-Wallachian (Rumanian), and Langue d’Oil. Rumonsh has two main dialects—the Overland dialect or Rumonsh proper, divided into two sub-dialects, the Sur-Selvian and Sub-Selvian, and the Engadine or Ladin dialect (see RÌÉTÌÀ). Yielding to the pressure of the vigorous Teutonic tribes, the Rhaeto-Romance races became at last confined to the solitary upland valleys, where they still continue to eke out a laborious existence. Their speech is also steadily yielding to encroachments and is gradually being supplanted, either by German or Italian. As the Swiss races differ in origin and language, so also do their temperamental characteristics. The French Swiss is active, vivacious; the Italian Swiss, fiery and irritable; the German Swiss, calm and thoughtful. Yet with all their racial and spiritual divergences, a fervent patriotism is common to all of the Swiss people. Independence and liberty are the keynotes of their existence. There is no desire among the German, French or Italian Swiss to be united with their neighbors of corresponding nationalities. It has been said that the Swiss as a people often suffer in the judgment of tourists by failure to live up to their reputation as a “mountain people” to a glorious “Alpine” character. In truth, however, the idea that dwelling in a mountain region has an ennobling influence on the human character is mostly fallacious. The Swiss are expected by the traveler to carry themselves in all things with the pride and dignity of people who are born and bred in the original home of European liberty. But civilizations and traditions of human freedom have always begun on the plains—by seashore and river bank. If all things denote the pride and dignity of people who are born and bred in the original home of European liberty, it is rather a handicap than an advantage to a race to inhabit a mountain country, for in the earlier stages of civilization the mountain fastnesses have imposed upon them the duty of shielding patriots and criminal fugitives from justice. In later stages, again, men who have achieved the machinery of civilization. It has been facetiously pointed out that mountain air sharpens the wit of the Swiss more than the wits, and there are diseases attacking particularly the brain which are almost peculiar to mountain districts. One favorable national circumstance of the Swiss is that their central position in respect to the great plains of Europe has put them in a position of a connecting link between the chief currents of civilization. What they have achieved in spite of the cap of their mountains is one of the marvels of the human race. To these natural barriers they owe in the main their sense of national unity. **Industries; Chief Towns.**—The Swiss depend for their support on various branches of industry, to which much attention has given of late years. There are now large and cotton factories, while the watch and clock industry established in Geneva since the 16th century has been long famous. Industries are: Embroidery; Besançon; chocolate (Suchard, Cailler, etc.), straw plaiting, wood carving, aniline dyes and aluminum. Asphalt is worked at Solothurn, and English company at Val de Travers and Château-Land. In the lowlands the chief occupations are agriculture, horticulture and wine growing. In the highlands almost the sole industry is rearing of livestock. The principal imports are cereals, fruits, vegetables, colonial produce, food substances, iron and mineral products. Being an inland country, Switzerland has commercial intercourse only with the surrounding states; but the trade with other countries, especially Great Britain and the United States, is very important. A source of enormous revenue is the catering for the thousands of tourists who invade the country. Switzerland is for its hotels, and it is no exaggeration to say that the Swiss are the most expert art of hotel-keeping. The large modern establishments at Geneva, Vevey, Zürich, Lucerne, Interlaken, etc., are models of the modern hotel; the smaller hotels are often equally conducted, and indeed a really bad inn is met with in French or German Switzerland. Normal times the prices are moderate. A flourishing occupation is the professional guide, who is indispensable for expeditions among the higher mountains, especially on those which involve the passage of glaciers. As a class, these guides are well treated and respectable men, well versed in antiquities and thoroughly acquainted with the laws and resources of the country. The mountain of the Swiss is strongly affected by the life of the tourist. The inhabitants generally well educated and proficient in languages. Offering asylum as it does to social rebels of all countries, Switzerland is a kind of international clearing house for thought and theory. For many years it has been the free and open laboratory in which the schemes of anarchists, Bolsheviks, Nihilists, free Masons, etc., have long been hatched. During the European War the Swiss were the mecca of diplomats, consuls and high-born refugees. The Gallic, th

f clerics, some 6,000, under nve bish-
hildren, and the official language is

greer which he does not adhere to.
ition of religious orders or new con-
prohibited.
swiss educational system is both gen-
practical (also for the six-
mentary school classes are mixed and contain
up to 45 children. The curriculum assures to
boys and girls a general elementary education
cluding a knowledge of French, while con-
instruction is given in music, physi-
carpentry, needlework and cookery. After
a four years' course the scholars enter the sec-
ondary schools, where they remain till 15.
A five years' advanced course in the sec-
ondary school the scholar has the option of
ultimately entering the gymnasium or the in-
dustrial and commercial schools. Up to the
age of 15 instruction is free; after that the an-
ual fees amount to 60 francs ($12). There
are great universities in the chief cities, which
are much frequented by foreign pupils. The
Swiss technical schools are second to none
in the world; they teach everything from waiting
at table to watch-making and science. In
mountain villages the schools are kept open
only during the long Alpine winter. All
through the summer the boys work in the fields,
while the masters and teachers attend to their
own farms. From the primary schools to the
higher the level of instruction is higher.
In the 4,690 primary schools there are about
350,000 pupils annually under 12,023
teachers. The cost of these institutions is lit-
tle over $10,000,000 a year. In the 642 higher
schools there are about 35,000 pupils annually
under 2,000 teachers. The cost of these is
about $1,500,000 a year. Besides these there
are schools of agriculture, dairying, commerce,
etc., while continuation commercial schools
give further instruction to some 10,000 pupils
yearly, who attend vacation and summer classes.
In the seven universities, Basel, Zürich, Bern,
Geneva, Lausanne, Fribourg and Neuchâtel,
there is an average of 9,000 students a year, of
whom fully a third are foreigners. An aver-
ge of 15,000 children a year are treated in the
rectorial schools, and some 1,300 in 28
schools for the feeble-minded. There are 14
special schools for deaf-mutes, with an average
of 700 pupils a year. Special attention is paid
in all Swiss educational institutions to gyn-
nastics and physical culture.

Government.—As already stated, Switzer-
land is a confederation of 19 entire and six
half cantons, which have been united for fed-
eral purposes since 1848. The present constit-
ution, which dates from 29 May 1874, vests su-
preme legislative and executive authority in two
chambers—(1) a State Council (Ständerath)
of 44 members, chosen two for each canton and
one for each half-canton for three years; and
(2) a National Council (Nationalrat) of 167
delegates of the Swiss people, chosen also for
three years by direct manhood suffrage, one
deputy for every 20,000 of the population.
Among the various forms of government de-
developed in Europe that of the Swiss federal republic has
been achieved by Switzerland alone. That
country may claim to possess the only truly
democratic government in the world.
The Swiss have produced great results with small
resources; they have shown that the plain
man can do in the way of government without
the help of a ruling class, of gentlemen of lei-
ure, of millionaires or of professional politi-
cians. An ideal democratic constitution should
make it impossible for political representatives
to impose on the country laws which the people
do not want. It should also be difficult, if not
impossible, for a small majority to impose constitutional changes to which nearly one-half of the electors are opposed. Yet these obvious requirements are conspicuously absent in democratic countries, for it is often uncertain how far laws, which are easily carried through a parliament or congress, are really wanted by the people, and whether, if put to the popular vote, they would have even a bare majority in the face of the opposition. The people as an aim of government is altogether lost sight of and party necessities become the sole motives of political action. Another requirement of democratic government is that the political machine should work as smoothly as possible, and for this end care should be taken so as to constitute the legislative and executive bodies as to avoid as far as possible the political crises consequent upon sudden changes of government and to minimize the turmoil or excitement produced by elections. The Swiss have solved these difficult problems with ingenuity and originality; they have evolved a political machine in which the frank and sure expression of the popular will and the smooth working and stability of government are obtained to far greater extent than in any other country.

Though the cantons are united together as a confederation or "Eidgenossenschaft" for mutual defense, each retains its individual independence and governs itself according to the constitution best suited to its own requirements. In these various constitutions there are gradations from the fullest democracy to the purest representative forms; but pure non-representative democracies have been adopted in the smaller cantons only, such forms of government being in fact impracticable except among small populations. The United Chambers, or as they are called, the Federal Assembly, to which is confined the supreme government. The executive authority is deputed to a Federal Council (Bundesrat) of seven members, elected for three years by the Assembly, the president and vice-president of which are elected annually, and are the first magistrates of the republic. The Council sits at Bern, which is the headquarters of the federal administration. Though ranking only fourth in point of population, Bern owes its status as capital (since 1848) partly to its central position in the Swiss Suhleland and partly to the historical importance of the canton, which is itself a result of that position. The principles of the referendum and of the initiative are in force. By former, if a petition is presented by 30,000 citizens for the alteration or revocation of a measure passed by the legislature, or eight cantons demand it, the law in question must be referred to the direct vote of the nation. The latter signifies the right of any citizen to demand a direct popular vote on any constitutional question. The federal government alone can contract treaties or declare war; it also controls the army, postal system, finance and customs. The cantonal authorities have jurisdiction over civil and criminal law, justice, police, public works and schools. The president is elected annually and receives a salary of $2,700; he is usually succeeded by the vice-president, whose salary is $2,000. A pension is paid to the other five members of the Bundesrat. These seven officials act as ministers: (1) Foreign Affairs; (2) Interior; (3) Justice; (4) Militia Finance; (5) Agriculture and Industry; (6) Posts and Railroads. The 44 member State Council receive about four dollars a day of attendance and an allowance for traveling expenses. Clergymen are not eligible to vote, but every citizen over 21 has the vote and is allowed to vote by direct vote. Out of 839,114 eligible, 1912, no fewer than 529,000 recorded their votes in a referendum held that year on insurance law against sickness and accident. Under the operation of the federal system, the Swiss, like the British, have a Cabinet, but unlike the American, has the right to be informed of legislation; but if a measure introduced having its support, is rejected by the Assembly in the order of their seniority on the agenda, the cabinet can veto it. Swiss elections are held every four years, and the number of Swiss presidents is fixed by law.
cantsons there is no special administrative machinery; all the male citizens assemble open air at stated periods and transact public business. These assembles are Landesgemeinde. The administrations in the larger cantons are carried on by regularly elected representatives; in most of the referendum exists, while some have a popular initiative.

Official System.—The Federal Tribunal or Gericht is stationed in Lausanne and is elected by 24 members, with nine supply judges appointed by the Federal Assembly. Their term is six years, and they may be elected. The president and vice-president hold office for two years and are not for re-election to those posts. The salary paid is $3,200 annually; the others, divided into three divisions, the trias final jurisdiction in all national suits; suits in cases where the value is in dispute not less than $600, and in appeal cases of $1,000. Civil suits are such in which constitutional divestive matters are concerned, internal disputes, or appeal against the decision of federal authorities. It tries treasons against the constitution, rebellion, and treason by various ways. The salary is $2,000 annually, and the president is paid two dollars.

For ordinary civil and criminal cases, there is an additional judge who has its own judicial system. Captivity was abolished in Switzerland by the constitution of 1874, but since 1879, there have been no reintroduced the death penalty, which now exists in the 10 cantons of the Inner-Rhoden, Fribourg, Lucerne, Glarus, Schaffhausen, Schwyz, Saint Gall, Wallis, and Zug. Nevertheless, capital punishment is not referred to in the Swiss code.

Switzerland derives its revenue from the alcohol monopoly, customs, railways, telegraphs, state property and investment in medicinal service, exemption taxes, revenue gathered for federal purposes, and so on. The revenue, normally, to about $32,500,000, about from the customs and almost the rest the public services. The production and sale of alcohol is a federal monopoly and produces about $1,000,000 annually. The proceeds of the latter are divided among the cantons, governments, who have to one-tenth of the amount received in the profits. The revenue for 1913 (last year) amounted to $30,000, and the expenditure to $21,002,000, to cost of mobilization and enhanced under war conditions the expenditure rose to $38,645,140 and the revenue to $4,400. The estimates for 1918 stood at $50,000,000 expenditure. For mobilization, government issued loans for $80,000,000 in 1914; $150,000,000 in 1915; $200,000,000 in 1916; $100,000,000 in 1917, and $150,000,000 in 1918. The public debt amounted to $1,490,010,000; including the debt of $2,427,000,000. There were 35 savings banks with 446,247 stockholders and $315,000,000 in deposits. In the total state property was valued at $29,000,000. The cantons separately hold $69,000,000, and the total of the country is normally about $50,000,000 annually. The salt monopoly produces about $7,500,000 a year. At the beginning of 1918, there were in circulation 10,880,000 gold coins of the face value of $40,520,000; 88,376 silver coins, face value $14,400,000; 143,700,000 nickel coins, face value $2,774,000 and 102,500,000 copper coins, face value $270,000—a total face value of $55,024,000. The national bank, opened in 1907, has the exclusive right to issue bank notes, of which it had in circulation on 30 March 1918 to the value of $139,125,860. Switzerland is a party to the Latin Monetary Union with France, Belgium, Italy and Greece. The franc is the unit of currency; its value in terms of United States money is $0.225, roughly 20 cents, or five francs to the dollar.

Swiss Army.—Compulsory universal service has been the root-principle of Switzerland's military system for centuries. Since the reorganization completed in 1912, the army has been brought to a high state of efficiency. The striking force of the Swiss army consists of about 300,000 men, divided into three parts: the Elite (20 to 32 years), the Landwehr (33 to 40) and the Landsturm (40 to 48), which numbers respectively 117,530, 108,900 and 68,000 men. The supplementary services (men of 20 to 48, not listed for the army) are paid for by a double number 205,000, and the Grand total of the whole army is slightly under half a million or one-eighth of the entire population. There are few exemptions except for physical disability and those excused or rejected pay certain taxes instead of rendering service. Liability extends from the 20th to completion of the 48th year; service is distributed as follows: 12 years in the Elite or "Auszüg"; eight years in the Landwehr and eight years in the Landsturm. The longest periods of training are the recruits' courses which every man goes through in his first year of service—65 days for the infantry, 75 for the artillery and 90 in the cavalry—besides which there are compulsory courses in shooting. The younger men (the first line) do seven other annual trainings of 11 days each (14 days in the artillery) before passing into the Landwehr, when they are called out for 11 days every four years; the Landsturm are only called up in time of war. Men convicted of have not been allowed to join the army and officers and men whose private life is unworthy of their rank and standing are court-martialed and dismissed. In the strictest sense a democratic service, the Swiss army is a model institution.
penditure is 11 francs ($2.20) per head of population, while 23 francs ($4.60) per head are spent on education. All men rejected for physical defects or exempted, teachers, clergymen, police, etc., pay a tax amounting in all the schools and cantons, and Service being the same for all, it is, the handicap for none. It interferes neither with personal liberty nor with the country's prosperity; it imposes little burden on the treasury and no burden at all on the content. In proportion to population Switzerland is one of the richest countries, as it has not an inch of territory beyond borders. The yearly value of Swiss commerce amounts to about $102 per head of the population, as compared with England, and the country not only being compulsory, but regards and affection the army which is its Owing to its inland position Switzerland no small fleet on Lake Zürich, with orders to oppose the French army, the latter, under Masséna, proved to be a success, and Russians, Williams calmly watch battle from the lake. Then, enraged at the inaction, he discharged his crews, scuttled vessels and took to flight.

History.—Switzerland is believed to have been first peopled by the Rhaetii, who were driven from the plains to the mountains by the Helvetii (q.v.), a Celtic tribe. The land is the oldest inhabitants of the country as is history; they were conquered by the Romans built military roads over the Alps and began to settle in the cantons of Avenches, in the canton of Vaud, which in the early centuries Christian era was the headquarters of man legion with its Rhaetian cohorts at Avenches, Houlte, Basel, Argovie, Saint Gall, Zürich and Schaffhausen. The sixth division (Italians and Romonches) is recruited from Ticino, the Grisons and Saint Gall. At the beginning of the European War all six divisions were mobilized so rapidly that in the first week of August 1914 Switzerland was able to post on its frontiers over 250,000 fighting men, well armed and well drilled. The infantry are armed with the Swiss repeating rifle. The field artillery consists of 75's and 120's (howitzers); the mountain artillery of 75's (1906 model) and the heavy artillery of 750's, firing a shell of about 39.68 pounds.

This national militia, which is not a standing army, is administered partly by the cantonal authorities, who have power to promote officers up to the rank of captain. The higher appointments rest with the federal government, which has charge of all general matters of importance. The Swiss consider it an honor to serve in the army and a misfortune to be rejected. Compassion and efficiency and the fact that it is raised by conscription, the Swiss army is a comparatively cheap one. The ex-
SWITZERLAND

1. Lucerne

2. Thun and the Bernese Alps
Switzerland had become a part of the
ish Empire, which did not take possession
ry with its own nationals, but
ed it through appointed officials. Chris-
 was introduced during this period and
omasities of Disentis (now a school); 
, named for Saint Gallus, an Irish
 and now a bishop's residence), and Ein-
 (now one of the most famous pilgrim
 in the world), were founded, and dukes
 and counts were appointed as vicerogents of
king's. Under the successors of
, Switzerland was divided: the
half was united with the duchy of
nia or Swabia (Schwaben), and the
part with the kingdom of Burgundy.

After the downfall of the latter in
the whole country fell to Germany, which
ed it through vicerogeents, the dukes of
agen. These governors in succession con-
emselves as princes, assumed the name
le castles, and compelled the free inhabi-
ty of Burgundy (districts) to acknowledge
 as their lords. They were in perpetual
 with the Burgundian nobles and con-
tly favored the inhabitants of the towns.
also founded several new towns, such as
m, Fribourg (Fribourg) and Burgdorf
out the Middle Ages, Switzerland and
ss were always in the eye of Europe.
es presented the spectacles of a
people repelling the tyrant and invader
unearthly courage and good luck; at
times it was that of a warlike clan, safe
great mountain fastnesses, offering their
bilities to the highest bidder and ren-
for pay as high a courage and stubborn
ity as was ever inspired by love of coun-
almost every European nation felt their
as enemies or allies. The Swiss was
at every court in some capacity. Peter
Prince of West Switzerland, built the great
castle in London, part of which survives
as the Savoy Chapel, built on the site
; he also built the famous Castle
 on Lake Geneva, immortalized by
, and kept great affairs going in both
far-apart countries. It is recorded that
velli prophesied that the Swiss would
day mark the site of present-day Switzer-
able enough then in the light of the
ble military virtue and energy of the
the power of the German emperors de-
d the nobles and priests were ambitious
pensibility and eager to enrich themselves
expense of their neighbors. Those of the
towns and smaller communities which
erved their freedom were compelled
raditions of safety to conclude treaties
feudal lords of the time. At the be-
the 13th century the three forest
of Uri, Schwyz and Unterwalden were
 to the then unimportant counts of Haps-
who, although they were properly only
al heiresses (Vögte), yet regarded them-
as sovereign rulers. This claim the three
constantly refused to admit, and eventu-
(1291) leagued themselves together to
the usurpations of the house of Haps-
Tradition says that on the night of 7
307, 13 Swiss representatives, with Furrin
son-in-law Tell, Stauffacher of Schwyz,
and Arnold of Melchtal in Unterwalden at
their head, met at Rüti, a solitary spot on the
Lake of Uri, swore to maintain their ancient
independence, and projected a rising of these
cantons for 1 Jan. 1338. On the day fixed
the rising took place, and the Austrian
herno were deposed and expelled. But the
events related of Tell are purely legendary. (See
Tell). A few years later the three cantons
were invaded by the Hapsburgs; but the signal
victory at the pass of Morgarten on 13 Nov.
1315, secured the independence of the cantons.
The three united cantons were joined by the
cities of Lucerne (1332) and Zürich (1351), the
cantons of Glarus and Zug (1332), and the city
of Bern (1333). Austria, which claimed juris-
diction over these of the newly-added members,
namely, the city of Lucerne and the cantons of
Glarus and Zug, again invaded the territory of
the confederation, but was completely defeated
at Sempach (where Arnold of Winkelried is said
to have sacrificed his life for the sake of his fel-
countrymen) in 1386, and in 1388 at Nafels.
The canton of Appenzell joined the confedera-
tion in 1411, and Aargau was wrested from the
Austrians in 1415. The third war with Austria
terminated in 1460, in favor of the confedera-
tion, which obtained Thurgau, Austria being
thus deprived of all its possessions in the regions
over which Switzerland now extends. Haps-
burg Castle still dominates the canton of Argau
—a monument of Swiss independence. In 1474,
at the instigation of Louis XI of France, the
Swiss turned their arms against Charles of
Burgundy, invading his country and defeating
his army near Héricourt. Charles, in revenge,
invaded Switzerland, but the Swiss inflicted
severe defeats upon the Burgundians at the	hree battles of Grandson, on the Vaud, Morat
(Murten) and Nancy in 1476 and 1477, in
the last of which Charles was slain. They admitted
Freiburg and Solothurn into the confederation
in 1481, and about the same time they con-
ducted defensive alliances with several of the
neighboring states. Their prosperity rose to
such a height that all the courts around, even
Austria, sought their friendship and alliance.
The last war with Austria broke out in 1498.
The Swiss had to undergo a severe struggle,
but, victors in six sanguinary battles, they were
by the Peace of Basel in 1499, practically sepa-
ated from the empire, a separation to which
formal and international sanction was given in
1648. That peace ended a triumphant strug-
gle of two centuries. After this war they had
no longer any enemy to fear, and their future
wars were waged on behalf of foreign powers.
In 1501 Basel and Schaffhausen, and in 1513
Appenzell (which had long been an ally), were
admitted into full federation. The number of the
cantons was brought up to twenty-four, at which it remained till 1798. The town
and the abbots of Saint Gall and the town of Bienne
had seats and votes in the diet without being
in full federation; and there were besides six
allies of the confederation not enjoying these
privileges—the Grisons, Valais, Geneva, Neuf-
châtel, Müllhausen, and the bishopric of Basel.
In 1516 France gave up to Switzerland the
whole of the present canton of Ticino. An alli-
ance between the two countries was formed which lasted until the French Revolution.
In 1518 the Reformation began to make its
way into Switzerland, chiefly through the efforts of Zwingli at Zürich. He fell at Kappel (1531), but his work was carried on by Calvin at Geneva. The effect of the Reformation for legislation and the government of the Swiss cantons "was at Wittenberg in 1517, when victory declared itself for the Protestants. The period of tranquillity that followed was alike favorable to the progress of commerce, agriculture and manufactures, and to the arts and sciences. In almost every department of human knowledge the Swiss of the 18th century, both at home and abroad, acquired distinguished reputation. In the last years of the century the ferment of the French Revolution spread to Switzerland, and in 1798 the ancient constitution was replaced by the Helvetic Republic, founded on the ruins of the ancient liberties of the nation, which lasted four years. In 1803 Napoleon I organized a new confederation, composed of 19 cantons, by the addition of Aargau, Grisons, Savoy, and Ticino, Thurgau and Pay de Vaud. In 1815, by the Federal Pact of Zürich Neufchatel, Geneva and Valais were admitted into the confederacy, and the number of the cantons was thus brought up to 22. This confederation was acknowledged by the Congress of Vienna, which proclaimed the perpetual neutrality of Switzerland, and the inviolability of its soil. Again in 1830 and in 1848, Switzerland was affected by the revolutionary movement in France, and a new federal constitution was introduced in the latter year. During the revolutionary commotions of 1848 Neufchatel set aside its monarchical form of government and adopted a republican one, and in 1857 it was put upon the same footing with the other cantons. Since that time the annals of Switzerland have little to record beyond the fact of constant moral and material progress. A revision of the federal constitution was adopted after a protracted agitation on 19 April 1874, from which time the cantons gradually adopted the referendum and the initiative. What this revision was going on of the individual cantons set the example of revising their constitutions. In this proceeding Zürich led the way, appointing a special council for the purpose in January 1868. It was followed by Bern, Aargau, Thurgau, Solothurn, and other cantons. All the modifications made were in a democratic direction. The chief opposition to the project of a revision of the federal constitution proceeded from the French cantons and the Ultramontane party, the former fearing that in consequence of a revision of the constitution in the direction aimed at, that of giving more power to the central authorities, they would be gradually Germanized, the latter believing that the influence of their party in those cantons where it was numerically strong would be curtailed. But in spite of this opposition the Federal Assembly, on 21 Dec. 1869, adopted the principle of a revision, and elected a committee to prepare a scheme for the purpose. The project of revision drawn up by this committee was laid before the Federal Assembly in the session of 1871-72, and after being accepted was submitted to the people on 12 May 1872, an article of the constitution then in force being adopted, adopted, he sanctioned by a majority of the people and of the cantons this occasion the 1869, and the 1870, by a majority; but a new one was drawn accepted on the date already mentioned, 1874. The new constitution gives more energy to the confederacy by asking federal authorities more power in relating to law, the army, the church, and nation. The laws of the various cantons are partially assimilated; the management of the national contingents to the army is no longer entirely to the cantons themselves; the astical authorities are completely subject to the civil power; and primary education compulsory and secular. Since then three partial revisions have been made. A constitutional modification, for instance passed by the National Council in 1891, effect that in future when a revision of the constitution, or the admission into new articles, is proposed by popular this proposal must be supported by the at least 50,000 citizens possessing a right voting, and not 30,000 as previously. The 600th anniversary of Swiss nationa celebrated. The more important events in Swiss of recent years may be briefly summarized: the last day of 1898 Switzerland was by the United States as a favored. In 1900 the nation rejected the "dou act," a scheme to elect members of the National Council by proportional repres. The new palace of the Swiss parliament opened in 1902. In the same year a future with Italy occurred. Agreement arrived at during 1903 for the constru the Jura and Simplon tunnels; a new was passed in 1907, when a British commission arrived at Basel to study the army system. In 1908 the sale and man of absinthe were entirely prohibited. country. During 1909 and 1910 a new age was caused by floods and avalanche recessive industrial development calls large supply of labor which Switzerland unable to supply; becoming every year of an agricultural country; means food have to be imported, while the factory hands has more than double years. The population of the country shows little increase; that of the to growing rapidly, mainly due to foreign immigration from Italy, France and, above a Germany. During the European War sion of Switzerland was one of extric -ity. Need of coal and iron comp republic to enter into an agreement with the Central Powers to supply them with fo. Besides maintaining its army on a war for the duration of the war, Switzerland came a clearing-house for the wounded and prisoners of all the b - while international diplomats and exis made it their headquarters. A not statement of Swiss policy was made in the somnium presented in February 1919 Federal Council to the Peace Conference. In this document emphasis was laid on Swiss neutrality, which is now according to circumstances, but is per
— a fundamental principle of the Swiss state since the beginning of the 16th century. As in the past, so in the future, Switzerland must remain the faithful guardian of the passes of the Alps. When all relations between the belligerents were broken off, Switzerland was able, thanks to its neutrality, to undertake the grateful task of carrying out a philanthropic activity which saved the world from an accentuation of its sufferings. Switzerland welcomed the creation of a League of Nations and, as the oldest of existing republics, would deem it an honor to bring into the League of Nations the experience acquired in the course of centuries. The determined insistence on neutrality by Switzerland—except in case of self-defense—places that country in a peculiar position with regard to the League of Nations. As pointed out by Professor Borgeaud in a pamphlet, "La Suisse et la Societé des Nations" (Geneva 1919), neutrality implies sovereignty, a principle inconsistent with the general spirit of the League. Nevertheless, indeed, the League in self-conceals this privilege for special international reasons. In a remarkable speech delivered before the National Council in August 1918 President Calonder first called attention to this point; though supporting intervention to end the war, he declared that Swiss neutrality prevented Switzerland from forcing itself as a peacemaker. Sturdy independence, freedom of action and avoidance of foreign entanglements or obligations is the keynote of the Swiss Republic. In a state paper dated 15 Nov. 1690 occurs this passage (in French): "The Swiss have two religions in their country, which divide them at times; but they have only one liberty, which they cherish above all: this reunites them always, and will reunite them for ever."

Editorial Staff of The American.

SWORD. The, a weapon used in personal combat for cutting or thrusting, one of the most ancient and highly esteemed of all weapons. No sooner had the art of working metals been discovered than it made its appearance, replacing almost at once the crude axe of the Stone Age. The earliest swords, of which any authentic records exist, were those of the Assyrians, the Gauls and the Greeks. These swords were double edged, straight or tapershaped, and were made of bronze, the art of tempering steel not having then been discovered. The Roman sword, which was made of steel, was short, straight and double edged, having its point cut at an obtuse angle. The swords of the Franks were straight, about 30 inches in length with a tapering point. None of these swords appear to have offered much protection to the hand. During the Middle Ages the sword was lengthened, while still retaining its general Frankish shape and quillons (cross-pieces) were added for the protection of the hand. A narrow-bladed sword called the estoc, used principally for thrusting, was often carried attached to the saddle by mounted men, the heavy sword being worn upon the person at the same time. A dagger called the misericorde (dagger of mercy) was worn on the right side by knights, and used to dispatch their fallen foes.

The German lanzenquenets, or mercenary foot soldiers, used a two-handed sword some six feet in length. On the march this ponderous weapon was worn slung over the back. In wielding the heavy swords of the Middle Ages, the forefinger was often hooked over the right quillon to strengthen the grasp. This forefinger being unprotected (except by the gauntlet) was frequently injured and so, for its protection, a little ring was placed in front of the quillon through which the finger was passed. For the sake of symmetry another ring of the same kind was added to the left quillon, the two rings being termed the "pas d'ane." Side rings
were next added for the protection of the hand and the right quillion was curved upward so as to form the "knuckle bow." A thumb ring was also sometimes added, the Germans being especially fond of this device. During the 16th century the rapier became much lighter, the striking of heavy blows having become less of a necessity owing to the discarding of armor on account of the invention of gunpowder. A cup-shaped guard was added to the quillons (which were generally straight, the knuckle bow being retained as a separate piece) and the weapon became a rapier, the point of which rather than the edge was used in making an attack. With the early rapier a dagger was worn, which when fighting was held in the left hand and used for parrying. Later a cloak was used for the same purpose. As the science of fencing became better understood, however, all secondary protections were discarded, and the rapier became a weapon of both offense and defense. Rapiers were often highly ornamented and the guards were frequently fanciful design. The best of them came from Spain, Toledo being especially noted for the excellence of her blades.

Shortly before the beginning of the 18th century the rapier was supplanted to a great extent by the colichemarde, a weapon with a hilt like our modern small sword, the marked peculiarity of which was that its blade was wide for about half its length and narrow for the other half. About 1760 the colichemarde gave way to the small sword, a very light weapon, having a small circular guard, a knuckle bow and a narrow straight blade. The foil used in fencing which represents the small sword is about 33 inches in length with a quadrangular blade and a bell or ring guard. Italian foils have quillons, French ones do not. The dueling sword is a heavier kind of foil, having a triangular blade tapering to a very fine point. A broadsword is a sword that has a cutting edge. It may be either straight or curved, single or double edged. It is essentially a military weapon and is in use in all armies. In the United States army a form of sabre is used varying from 30 to 34 inches in length. In the Confederate States the broadsword has come into disuse among infantry officers owing to the lack of opportunity for its employment in trench warfare and the dangerous distinctiveness which it gives to those who bear it.

The sabre which is the best known form of broadsword is single edged. Its blade, which is usually somewhat curved, is thickest at the back, from whence it becomes gradually thinner toward the edge. Its guard consists of a strong knuckle bow often terminating in a solid piece, which simply protects the hand. The scimitar, a light form of sabre having a very pronouncedly curved blade is the favorite weapon of the East. Damascus was formerly noted for the excellence of her scimitar blades. The cutlass is a heavy broadsword which is in use by most of the navies of the world. The machete, a weapon much used in Cuba, is shorter than the cutlass and lacks the protecting guard for the hand. The claymore, which may be called the national weapon of Scotland, is a heavy straight broadsword having a very elaborate basket hilt.

The schlaeger, the weapon used by the German students in their university duels, is a long straight sword with a very sharp edge, having a solid metal guard which completely encases the hand. The sword bayonet is a short sword adapted for use either with or without the rifle.

The long sword of the steppes was much lighter, the striking of heavy blows having become less of a necessity owing to the discarding of armor on account of the invention of gunpowder. A cup-shaped guard was added to the quillons (which were generally straight, the knuckle bow being retained as a separate piece) and the weapon became a rapier, the point of which rather than the edge was used in making an attack. With the early rapier a dagger was worn, which when fighting was held in the left hand and used for parrying. Later a cloak was used for the same purpose. As the science of fencing became better understood, however, all secondary protections were discarded, and the rapier became a weapon of both offense and defense. Rapiers were often highly ornamented and the guards were frequently fanciful design. The best of them came from Spain, Toledo being especially noted for the excellence of her blades.

Sword-Dance. See Frikilege, under Ferns and Fern Allies.

Sword-Fish. See Globoideus.

Swordfish, an enormous mackerel-like fish (Xiphias gladius), representing alone the world-wide family Xiphidae. It has an elongate mackerel-shaped body which may equal in size that of the largest sharks, and whose muscles are astonishingly strong. A powerful forked tail, a lofty sail-like dorsal fin, and a long, cord-like anal fin are prominent in adults, but continuous in the young, and other strong fins, give the creature a power and speed in swimming equaled by few oceanic animals. The skin is naked, more or less rough, and the flesh red in color and rich in flavor. It is greatly enjoyed when eaten. These fishes are predatory, obtaining their food by fierce forays upon flocks of lesser fishes. Their strength and sharp teeth are supplemented by the prolongation of the fore part of the skull into a horizontally flattened "sword," composed of the consolidated vomer, ethmoid, and premaxillary bones. The excellence of this weapon and the power of attack is attested by the frequent piercing of boats and even of large wooden ships, through which the sword has been deeply thrust before breaking off. Although occasionally seen in the Pacific, the swordfish is characteristic of and numerous only in the North Atlantic, the Mediterranean Sea, and about the Antilles, where in summer it approaches the shore, in pursuit of schools of spawning fishes, and itself becomes the object of a profitable fishery, especially in Italian waters. Along the northern seaboard of the United States this is regarded as a prime summer sport. The fishermen cruise a few miles from the coast in small schooners, hav-
ing at the extremity of the bowsprit (from which the jibboom has been removed) a small plate carrying a belt-like rail of iron at the height of a man's waist, within which a harpooner may stand securely while his arms are free. Having sighted a swordfish, visible by its projecting backfin, the vessel is steered up and a harpoon is thrown accurately which is attached by a rope by which the catch is hauled aboard. Consult Goode, G. B., 'Fishery Industries' (Washington 1884).

SWORDS, Order of. See Orders (Royal) and Decorations.

SYBARIS, sib'a-ris, an ancient Greek city and colony of Lower Italy, in Lucania, on the Gulf of Tarentum, not far from the site of the later town of Thurii. Tradition ascribes its building to a colony of Achaeans and Thessalians about 720 B.C. It rapidly rose to a high degree of prosperity, but enervated by the mildness of the climate, the richness of the soil and their great wealth, the inhabitants became pro-

verbial for their luxury and voluptuousness. In a war with Crotona the city of Sybaris is said to have brought into the field 300,000 men, while the spoil of the former amounted to 100,000. The Crotonians, however, were victorious and totally destroyed Sybaris by turning the waters of the river Crathis against it (510 B.C.). The inhabitants of the town dispersed themselves for the most part over the other Greek cities of Lower Italy. Sybarite is still used to signify an effeminate voluptuary. In 1879 and in 1887 excavations revealed two great cemeteries but the true site of the city remains undetermined. Consult Notizie degli Scavi (Rome 1879-88) and Orsi, P., 'Atti del congresso di scienze storiche' (Vol. I, Rome 1904).

SYCAMORE, sikk'a-môr, Ill., city, county-seat of DeKalb County, on the Chicago and Great Western and the Chicago and North-western railroads, about 55 miles west of Chi-

cago. The city was founded in 1836. It is an agricultural and stock-raising region and has considerable manufacturing interests. The chief manufacturing establishments are flour mills, in-
sulated wire works, brick and tile works, sash and

factory windows, carriage works, agricultural implement works, varnish and furniture factories, canning establishments and creameries. There are large establishments for preparing fruit and vegetables for shipment. There are church, a young ladies' seminary and public graded schools. The national bank has a capital of $50,000; there is also a private bank. Pop. about 3,800.

SYCAMORE, a name applied originally to Ficus sycomorus, a tree known in biblical times and places, and the legendary one chosen by Zacchaeus to climb into for a sight of the Saviour. It is a species of fig, an evergreen timber tree, flourishing in Egypt, which sup-
plied an inferior coarse-grained wood for ordi-
nary purposes and for mummy cases. A famous Egyptian statue of an infant, Osiris, is on trunk and branches, edible and sweet-flavored and is a large item of food among the lower classes.

The ripening of the figs is hastened by making incisions in the apexes. In the Middle Ages a European maple, Acer pseudo-platanus, was selected to represent the tree of Zacchaeus in the old miracle plays, on account of it dense foliage. It is a tall, very handsome tree of quick growth and living for perhaps 200 years. The leaves are large and have acute lobes, somewhat resembling those of the plane, and the yellowish flowers droop in terminal racemes. The bark is smooth, often peeling off in large flakes, leaving patches of lighter color. The sap is saccharine and the wood is hard and white, although with a brownish heart, and takes a fine polish, being used by wheelwrights, turners, cabinet-makers and wood-carvers and for musical instruments. Sycamore endures sea and mountain winds better than most timber trees and is, therefore, planted for its shade in exposed places. Certain of these trees in Scot-
land were known as dool-trees, or grief-trees, because they formed informal gibbets on which to hang the enemies of thegovernment. Perhaps because of the likeness in foliage and the stripping of the bark, the name of syc-
amore has been again transferred to the Ameri-
can plane-tree (Platanus occidentalis) better known as buttonwood. The American trees with awkward, twisted, wide-spreading limbs which, however, when the tree is fully leaved out, forms a broad pyramidal head. The bark is smooth, that of the upper portion flaking off in pieces each year, leaving whitish patches, which are very conspicuous in winter. The large leaves range from simple coarse-toothed to distinctly dentoid and three-
lobed blades. The flowers are clustered in compact round balls, with from three to eight minute petals and sepals; the fruit-heads retain this globose form and are composed of obpyramid-
al nutlets, having long, nearly erect hairs at the base. They are usually solitary and swing on long peduncles during the winter, only fall-
ing apart in the early spring. The reddish-
brown wood is chiefly useful for cigar-boxes and is compact and difficult to split or to work. The Australian sycamore are Sterculia lurida and the white sycamore (Cryptocarya nov-
vata), one of the native nutmegs, and a large tree yielding serviceable white timber. Melia azedarach is the false sycamore, the large tree more commonly known as the pride-of-China tree.

SYCEE (si'sé') SILVER, the fine silver of China, cast into ingots weighing commonly rather more than one pound troy. They are marked with the seal of some banker or as-
sayer as a guarantee of purity.

SYCOSIS, a putrifiable disease of the skin of the bearded face. It is often called barbers' itch (q.v.) and may be regarded as a form of that disorder. The usual treatment consists of application of carbolic acid, zinc ointments, ichthyol, sulphur or oil of cade.

SYDENHAM, Charles Edward Poulett Thomson, 1st Baron, British statesman and governor-genius was carved out of a block of sycamore wood about 4000 B.C. The thick foliage, resembling that of the mulberry, makes the sycamore a desirable shade-
tree and it is still planted for this reason in Egypt. It is most of all by fruit and branches, edible and sweet-flavored and is a large item of food among the lower classes.
which he in 1834 became president and treasurer of the Navy. He became a recognized authority on financial matters and he was an earnest supporter of free trade. He was appointed governor of Canada in 1839 and it was under his administration that the union of Upper and Lower Canada was effected and a new constitution established. For his services in connection with this difficult undertaking he was in 1840 granted a pension of £1,000. He was preparing to return to England when he met his death during a hunting accident. Consult Poulett-Scrope, G. J., "Memoirs of Charles, Lord Sydenham" (1843).

SYDENHAM, Thomas ("The English Hippocrates"), English physician; b. Wynford Eagle, Dorset, 10 Sept. 1624; d. London, 29 Dec. 1689. He entered Oxford University in 1642 but his studies were interrupted by service as an officer in the Army of Parliament. He graduated in 1648 and was elected a fellow of All Souls College, but his medical studies were again interrupted by military service. He began practice at Westminster about 1655, for some time still giving much attention to politics. He was afterwards elected by the Royal College of Physicians in 1663 and took his M.D. at Cambridge University in 1676. While his medical studies were much interrupted and his early practice was without a medical license he made remarkable progress. He developed powers of diagnosis amounting to genius and he followed the method of Hippocrates in watching the progress of the patient and assisting nature in its effort to throw off disease. His theories were backed by his notable success in treating patients; and by his strong sense and plain manner of dealing with matters hitherto cloaked with professional mystery. He also kept mainly to simple prescriptions instead of the involved sort in vogue. He received recognition from abroad comparatively early in his career, his fame being largely augmented by his writings; but he made many enemies in the medical profession at home, although he also enjoyed the loyal support of many members of his profession. He made important contributions to medical science in his study of gout, of which he was a victim; his observations of epidemic diseases through a number of seasons and distinguished several that were formerly confused; introduced the cooling method of treating smallpox; was the first to use a tincture of opium, laudanum; and initiated the use of Peruvian bark in treating malaria. His scorn for dogmatic theories was intense and he was known in the case of a patient whose strength had been vitiated by the weakening processes of the day to prescribe food instead of medicine—an unheard-of procedure. His doctrines came into full recognition in the early part of the 18th century, it was then that the custom of designating him the "English Hippocrates" was inaugurated. However, while he felt keenly the antagonism evinced toward him by many members of his profession, he enjoyed a universal spiritual of the highest order and never suffered the ostracism endured by many pioneers in the new theories of medicine. Author of "Observationes medicæ" (1676); "Tractatus de podagra et hydrope" (1683); "Schedula monitoria de novae febris ingressu" (1688); "Proc.

ed ports, led, in 1901, to the formation of a port overseers, led, in 1901, to the formation of a port trust. This commission oversaw all the wharves, docks, and wharves, and considerably improved shipping at Sydney has 103½ miles of electric railway, which is mostly under municipal control.

SYDNEY, Canada, city, chief port of entry from which the capital of Cape Breton, province of Nova Scotia, situated on the westernmost part of Sydney harbor, 285 miles from Halifax; and on the Inter-

SYKES, Frederick Henry, American college president: b. Queensville, Ontario, 13 Oct. 1863; d. Cambridge, Mass., 14 Oct. 1917. He was graduated at Toronto University in 1885, and in 1891-95 was student, scholar and Fellow at Johns Hopkins University, where he took his Ph.D. in 1894. He was engaged in teaching in 1895, and in 1903 became professor of literature and director of extension teaching at Columbia University; and was professor of English and director of technical education at Teachers' College, Columbia, in 1903-13. From its organization in 1913 until 1917 he was president of the Connecticut College for Women. He was general editor of Scribner's 'English Classics Series'; and author of numerous textbooks on English composition and of 'French Elements in Middle English' (1890); 'Syllabus of Lectures on Shakespeare' (1903); 'Lectures of the History of English Literature in the Nineteenth Century' (1904), etc.

SYKES, George, American soldier: b. Dover, Del., 9 Oct. 1822; d. Brownsville, Tex., 9 Feb. 1880. He was graduated at the United States Military Academy in 1842. He was engaged in the closing scenes of the Seminole War and later in Texas, and served through the Mexican War. He was afterward on duty at western army posts and engaged in Indian warfare, and in 1855 was promoted captain. He was commissioned major of the 14th United States Infantry soon after the outbreak of the Civil War, participated in the battle of Bull Run, was commissioned brigadier-general of volunteers 28 Sept. 1861 and major-general 29 Nov. 1862. He commanded the Fifth Army corps at the battle of Gettysburg, and in April 1864 was transferred to duty in Kansas. He was brevetted brigadier-general in the regular army in 1865 in recognition of his services at Gettysburg and throughout the war. He became colonel of the 20th Infantry in 1868, and spent the remainder of his life at different western army posts. Congress appropriated funds for his burial at West Point, where a monument was erected to him.

SYLLABUS, a document issued by Pope Pius IX, 8 Dec. 1864, which condemned 80 current doctrines of the age as heresies. It is a summary or collection of errors previously repubhshed in various allocutions and encyclicals. It is a condemnation of the intellectual, social, and religious heresies, characteristic of modern times as these are in opposition to Roman Catholic doctrines. It was divided into 10 chapters, each containing several propositions with reference to their previous condemnations, under the following general heads: (1) Pantheism, Naturalism and Absolute Rationalism; (2) Moderate Rationalism; (3) Indifferentism and Latiudinarianism; (4) Socialism, Communism and Secret Societies; (5) The Adversary Supremacy of the Civil Power over the Church; (6) The right of the State to interfere in Spiritual things; (7) Morality independent or religious sanction; (8) The Sufficiency of merely Civil Marriage; (9) The Denial of the Temporal Independence of the Papacy; (10) Falsely styled *Liberalism.* The Syllabus Errorum was the occasion of much controversy and was seized upon by the German government as a pretext of
the famous May Laws against the Roman Catholic Church in that country. The syllabus reas-
serts all the claims of the mediæval papacy. It provoked conflict between the papal and the
civil power in Prussia, Austria and Brazil. "Syllabus" is the name also used for a decree
of Pius X (1907), condemning modernism in 65 propositions.

SYLLOGISM, in logic, an argument stated in full logical form, so that its conclusiveness
is manifest from the structure of the expres-
sion alone, without any regard to the meaning
of the terms. A perfect syllogism comprises
three and not more than three propositions, the
third being the one to be proved; this is called
the "conclusion"; the other two, called the
"premises," contain the means by which the
conclusion is arrived at. A syllogism may be represented thus in symbols,

All A is B.
All C is A.

All C is B.

Or with words instead of symbols:

All metals are elements.
Internal is a metal.

All metals are elements.

This syllogism is valid, because the conclu-
sion logically follows from the premises. For the "figures" and "moods" of the syllogism and
the rules for the construction of syllogism see
LOGIC.

SYLPHS, in ancient mythology, the name
given to the elementary spirits of the air in the
polytheistic-pantheistic system of the Paracel-
sists. The sylphs, like the other elemental spir-
its—the salamanders or spirits of fire, the
gnomes or spirits of earth and the undines or
spirits of water—form the link between im-
material and material beings, for though, like
men, they eat, drink, sleep, travel, sicken and
beget children, they resemble the more elevated
spirits in the liveness and transparency of their
bodies and their rapidity of movement; they
also know more of the present and the future
than man does. They have no soul, and there-
consequently suffer annihilation after death. Con-
sult Paracelsus, Liber de Nymphis, Syphs,
Pyrmis et Salamandris et Ceteris Spiritibus (Basel ed., 1590).

SYLT, silt, Germany, an island in the
North Sea, near the coast of Schleswig-
Holstein. It is 22 miles in length, and has an
area of 40 square miles. It consists largely of
sand dunes with some cliffs—especially near
Kamper. The Friesian inhabitants are chiefly
occupied in agriculture, stock-raising and duck-
trapping, and are renowned as stilt sailors.
The dialect is peculiar, but German is the school
and church language. The principal town is
Keitum; the port is near Munkmarsch, con-
nected by rail with Westerland. Lighthouses
stand between Wemmestadt and Kamper and
on the northern point of land. There is good
sea fishing about.

SYLVANITE, a native telluride of gold
and silver, containing 24.5 per cent gold and
13.4 per cent of silver. It usually occurs mas-
sive, but is often seen in curious skeleton
.crystalizations, due to twinning, and somewhat
rare ways, within Mica Schists, giving rise to the name, "graphic tellurium." In
individual crystals are rare and of highly com-
plicated, monoclinic forms, with perfect clio-
Pinocaidal cleavage. It is brittle; fracture un-
even; hardness only 1.5 to 2; specific gravity
very high, 7.9 to 8.3. Its color is usually silver-white or slightly yellowish;
streak gray. It is an important ore of gold
and silver in Transylvania (whence its name),
Colorado and California.

SYLVANUS, syl-ván’ús, in Roman mythol-
ogy, a rural deity, who is represented as half
a man and half a goat.

SYLVESTER, James Joseph, English
mathematician: b. London, 3 Sept. 1814; d.
there, 15 March 1897. He was of Jewish
parentage and was educated at Cambridge
University, where, however, his religion prevented
his taking his degree until after the passing of
the Tests Act in 1872; but he took his degree at
Trinity College, Dublin, in 1841. He became
professor of natural history at the University of
London in 1837; and in 1841 was called to the
chair of mathematics at the University of
Virginia. He remained there but a short time,
his frank expression of his opinion of the slav-
ey question making his stay impracticable.
He was connected with a firm of actuaries in
London in 1845-53, meantime writing brilliantly on
mathematics. In 1855-70 he was professor of
mathematics at the Royal Military Academy,
Woolwich. In 1877-83 he was professor of
mathematics at the newly-established Johns
Hopkins University; and while in America
he founded and was the first editor of the Ameri-
can Journal of Mathematics. He was called
in 1883 to the Savilian chair of geometry at
Oxford University and retained it until his
death, although he was not on active duty from
1892, when his sight failed. From 1870 he was
recognized as one of the leading mathematicians
of the world. He published a vast amount of
original work, chiefly in the form of contribu-
tions to scientific periodicals and to learned
societies. His researches dealt principally
with algebraic forms, although he also made con-
tributions to analytical and pure geometry,
mechanics, optics and astronomy. He exerted a
profound influence upon the study of higher
mathematics in America as well as in Europe,
and his genius as an inventor of mathematical
was accompanied by remarkable facility in in-
structing and inspiring his students. He was
also an able linguist and was deeply interested
in verse making, although he failed to make a
name in that field. He wrote in this connec-
tion 'The Laws of Verse' (1870). He was
elected a Fellow of the Royal Society in 1839
and was the recipient of many honors from
universities and learned societies both at home
and abroad. His mathematical works were
edited by Baker, H. F., 'Collecte Mathematical

SYLVESTER, syl-vé’s’tér, Joshua, Eng-
lish poet: b. 1563; d. Middleburg, Holland, 2
Sept. 1618. He is remembered by reason of his
translation, into English of the "Divine Weekes
and Workeis" of Du Bartas, a French Humanist
nobleman. It was especially popular with the
Puritans in both the Old and New World, and
was one of the sources of inspiration for Mil-
ton's 'Paradise Lost.' Anne Bradstreet, the
"First New England Poetess," was a noted em-
asteous admirer of Du Bartas, known to her
through Sylvester's version, and modeled her
SYLVESTER—SYMBOLISM

SYLVESTER, See Sylvester.

SYLVITE, native potassium chloride, KCl, isomorphous with halite or common salt, crystallizing in the isometric system. Its habit is cubic, the crystals often modified by the octahedron. It usually occurs in granular or columnar masses, or compact. The crystals have perfect cubic cleavage, fracture uneven, brittle; hardness, 2; specific gravity, 1.98; lustre vitreous; usually colorless or white; transparent when pure. It is soluble in three parts of water and tastes slightly more bitter than common salt, like which it is highly diathematic. It is mined in Sicily and very extensively at Sussfurt and Leopoldshald in Prussia, the production in 1902 amounting to 181,341 metric tons. It is used in the manufacture of potassium salts, especially the nitrate (saltpetre) and the carbonate (potash). It is also called sylvine and sylvicite. See Potassium.

SYLVIA, Jacobus (Latinized name of Jacques Dubois), French anatomist: b. Amiens, 1478; d. Paris, 14 Jan. 1555. He early devoted himself to mathematics and the learned languages, but in middle life turned to medicine and took his degree at the University of Montpellier, later entering the University of Paris at the age of 51. He taught anatomy at the college of Tréguier, and later at the University of Paris. He is generally credited with the invention of the use of injection in dissection, but it is said he taught it evidence points to its being known before he used it. He appears to have been an ardent disciple of Galen rather than an original investigator, but gained a great name in his profession. The Sylvian fissure, the Sylvian aqueduct and the Sylvian plexus are named for him.

SYMBIOSIS, a biological term introduced by De Bary to denote intimate and complementary partnerships between different organisms, as between the algoid and fungus elements in lichens, or between unicellular algae and radiolarians. A great number and variety of cases of symbiosis have been recorded among the lowest plants, but botanists find the subject more and more obscure and their decisions are by no means general. The effort to differentiate symbiosis from commensalism and parasitism has proved most baffling in many cases. The term "social symbiosis" has been given to the association of insects found in the communities of ants, bees, termites, etc., where many small aphids, beetles, etc., not at all related to their hosts, dwell in peace and in some cases seem to contribute to the general welfare as well as receive benefits. The subject has been discussed mainly in Germany. Consult Brandt in Archiv für Anatomie und Physiologie (Leipzig 1882); Hertwig, Oskar, 'Die Symboles' (Jena 1890); Keeble, Frederick, 'Plant-Animals: A Study in Symbiosis' (Cambridge 1891).

SYMBOL, a word of various meanings, derived from the Greek word symbolon, a sign, or symbola, a composition. In the early period of Christianity the word was often applied to the Creed and to the sacraments. It is also used to indicate, either in a religious or profane sense, an emblem, figure or type, something which specially distinguishes one regarded in a particular character, or as occupying a particular office, or holding a special place in legend or mythology, as a connotation, the trident which is the symbol of Neptune. See Symbols, Astronomical; Symbols, Chemical; Symbols, Mathematical.

SYMBOLIC LOGIC. See Logic, Symbolic.

SYMBOLISM. The word symbol is derived indirectly from the Greek symbolon, a sign or token. Symbolism is the art and doctrine of symbols; it is the knowledge of the treatment of symbols or of deciphering the occult intent of signs or symbols and especially in reference to things spiritual, a sign or token, which can or cannot be pictured, as with ideas, qualities, etc. To the Greeks the word symbolon meant signs of such clearness that the allusion and the object were practically coincident. Among the Greeks their hospitality ended in giving their guests, or exchanging with them, a memorial of the visit in the form of a wooden tablet, a die or a ring, broken into two pieces. The host retained the other half, and in case of a future meeting presentation of the halved token was a sure identification as one half fitted exactly into the fracture of the other half of the symbolon. It is claimed by authorities that the origin of symbolism is traceable to the hieroglyphics or pictorial writings of the ancient Egyptians and was transmitted from them to other nations by the Jews. The Egyptians symbolized their gods with animal forms or combinations of both human and animal form; thus Horus, the sun-god, took the form of a sparrow-hawk, the disc was the hieroglyph of the sun, hence the disc and the sun survived from the Assyrians, has its clear definition, and expressed also the victory of good over evil. The snake (uraeus) was symbol of death, hence, used as an attribute of the Egyptian kings, meant power of the living and death, just as the handled cross (ankh) seen held by gods and kings signifies life. The staff (was) was the Nile kings' symbol of authority and has retained that significance with most nations ever since. From insect life also the Egyptians obtained such important symbols as the scarab (Scarabaeus sacer), the "sacred beetle," which they worshipped as a symbol of divinity, carving its form on finger rings containing inscriptions to be carried as an amulet. As to the mythology of the ancient Greeks and Romans it is not clear to us whether at first they looked upon their gods as symbolic of the elements of the world surrounding them; certainly it is that they embody a very perfect system of the symbolism of Creation. With Uranus, god of the heavens above them, wedded to Gea, the broad-chested earth, bringing forth Cronus, god of the harvests, and Zeus, the light of heaven, springing forth from the heavens god; with the storm-siege tower mountain top of Olympus dedicated as seat of the gods and realm of the divine brood, poetic symbol-
ism could get no closer to the human accounting of nature. Contemporary writers appear to show the acceptance of the theogony as alle

goric if not symbolic, and symbolism played a big role in the mysteries and in orphism. And the Neo-Pythagoreans under Plotinus, Porphyry, Proclus and the Emperor Julian, etc. found by the ridicule and logic of the Christian apolo-
gists to acknowledge that Saturn, Jupiter, Mars, Minerva and Venus were but symbols under which with other myths they represented divine attributes and manifestations. Leaders in the

modern schools of learning begin to see that it is symbolism that is expressed in the mytholo-
gies of Egypt and India as well as of Greece and Rome. But the most universally practised
worship has been that of the sun-god, whose symbol, the swastika, dates back earlier than the Sanscrit, and which symbolic cross has always been a sacred sign and known as the "Wheeling cross" or "wheel of the law" with Buddhists. Representing the sun, when its hands point to the right, an ancient symbol of the earth's revolution in easterly direction when the hands point to the left (some times then termed suavastika), it is found as an ancient symbol all over the American continent, on pottery of our prehistoric races. In a slightly varying form this swastika, known as the "swajot", appears among the ancient Celts as a favored symbol, occurring very frequently among the Scandinavian nations of early days. Symbols such as the triskelion, tetraselvex, etc. are interesting but belong to the subject of symbols, not symbolism now under discussion. The Chinese live in an atmosphere of symbol-
ism, every decoration having symbolic motifs as the chief characteristic, and even the shapes of the vases and jugs are symbolic. Scattered all over their pottery, porcelain, bronzes and enamels we find such symbols as those of longevity: Kylin (unicorn), kwei (tortoise), ho (crane), lau (deer). Their mystic number eight, (Fa) shows forth in the Pa-pao or eight precious things; the Po-kwai or eight mystic trigrams, the astrologers' symbols; the Po-chi-

siang or eight Buddhist symbols, etc. From the vegetable kingdom they find symbolism in the peach (toa), token of marriage and longevity. Another symbol condition is also symbolized in the gourd (hu-lu) and the fungus (chi); and the bamboo (chih), pine (sung) and plum tree (mey) are symbol of three friends. With the Japanese symbolism is a large part of their life. Among such we find: A pine, bamboo, orchid and a chrysanthemum symbolize the "four wise men" of Confucius; a pine twig, wisps of straw and a red lobster are a New Year symbol combination; a moon, snow flake and a flower in conjunction are symbols of the changing conditions of nature.

Jewish Symbolism.—Like all other Oriental peoples the Jews practised their system of symbolism. Many symbolic rules and for-

mule occurred in the building of Solomon's Temple, if the result of the researches of the Pseudemus can be relied on. The rending of Jeroboam's garment by the prophet Ahijah implied the separation of Israel from Judah; the rainbow presented a sign or symbol of the pact between God and the earth; the law of circumcision was a symbol of the covenant of the body. Josephus writes that the high priest's vestments were in every detail of sym-

intent, the coat symbolizing the earth; the garment, heaven; the belly and pomegranate thunder and lightning; the ephod, the fu-

ments; and the interwoven gold, the glo-

God, the 12 Jewels of the breastplate, the stars of the zodige. Or as congregating the significance are the blood of the Paschal shearing of the hair of the Levites, wa-

and bathing and anointing as a ritual, th-
ing on of hands, etc.

Christian Symbolism.—While the re-

tive Christians in the Roman Empire used symbolic language of signs, this was not as a matter of choice but of necessity. Persecuted sect could not safely, even in Catacombs, express themselves in their writings on sarcophagi or chapel walls with comment; they had to hide their epistles, other written or depicted statements in that would not draw down destruction on Any originally conceived system of symbol expression, while having the congre-
gation doctrine would have brought some among the authorities as to the intent of strange symbols. Therefore we find these worshippers of the cross using an eagle, R symbol of Jupiter; they borrowed from signs of the zodiac, from symbols appa-

in the pantheistic mysteries, etc. And they, later, used the sign of the cross in half hidden in combination with an and symbol used by the pagans. A crude for a fish (now called a garuda or a mandorla) came symbol of Christ referring to a sim of sound, icthys the Greek word for fish from the fact that the letters therein serve as the Greek initials of the words: Christ, Son of God, Savior. The vine bute of Bacchus) was adopted as a symbol of Christian promise. The lamb, the palm Good Shepherd, would all be understood heaven contemporaries in a different sent than in the Po-pao or eight things; the Po-bao or eight things by the early Christians. Greater safety in the use of sy was afforded the Christians from the fact there were other persecuted sects with Roman Empire, who, for their forbidden initiative a well-developed system of use in public communications to the lows, a language undecipherable to the tiate. Inscriptions of these symbolic sions are found cut in the vast rock temp Egypt, in Syria, Asia Minor, Sicily, Great Britain and in France. A method of cating a knowledge of this sign language with the cult, was carried on unber by their persecutors. They formed them into literary societies, guilds, burial s, etc., all under license as legal colici, but secretly active as congregating doctrine propaganda instead of the absence gatherings. Among the systems of bolism adopted by the early Christians those belonging to the Pythagorean and tical doctrines and the sacred number 8 among them. But from 325 A.D. such was a state offense. Augustine made the symbolic language and declared it a ateristic of the Gnostics. This latter coming into existence after Gregory had already envisaged openly, endeavored to cut its principles with the Greek philosophy.
SYMBOLISM

such teachers as Saturninus, Basilius and Valentine a very extensive symbolic language was created in the Byzantine period and practised by these Gnostics, but the full intent of the expressions of this cult is lost to us at this day. Byzantine art discloses a considerable proportion of its symbols, such as the Abrazas, etc. As a matter of fact there is a close connection between Byzantine Christianity and Mithraism, from which much was derived, even if in changed form. And Byzantine art is built up entirely of symbolism, even to its very architecture, and it frequent lack of beauty from an artistic point of view is caused by its occultism in form and manners. Unlike the pagans, the Christians in their practice of symbolism always clearly distinguished the conventional signs from the divine and sacred essence they represented in their ceremonies or sacraments.

In covering the catacombs with such depicted figures as fish, lamb, shepherd, grapes, fountain and hart, ship sailing safely on rough seas; with theirprung to Chi Rho (“sacred monogram”), Alpha and Omega, etc., they set up no figures for idolatrous worship, but simple symbols of spiritual truth. C. S. Lewis characterized the ecclesiastical symbolism were Hugo of Saint Victor, Richard of Saint Victor, Vincent of Beauvais, Durandus, bishop of Mende, Languedoc, Honorius of Autun, Sicardus of Cremona, etc.

Symbolism attained its apogee in the Middle Ages, when animals, colors, plants, lines and attitudes had their hieratic significance. Candles, symbolic of the Light of the World, found ubiquitous use in all rituals; the vestments of the clergy, besides the ritual itself, were symbolic. The Church also had its representation in a woman crowned and majestic, bearing the banner of victory and the chalice, while Judaism, as unbelieving, took the form of an aged woman holding a cracked staff, the tables of the law falling to earth, her eyes bandaged and her crown toppling from off her head. Art was fond of depicting the universality of life’s uncertain tenure by illustrating the title of Death, a human skeleton calling, as unwelcome visitor, on king, queen and humble peasant. The books of Bestiaries afford us an insight into the allegorical or mystical significance of the most grotesque, monstrous animals of those days of superstitions. They figure on the gargoyles and in the moldings of Romanesque and Gothic structures. Much of the beauty of Gothic architectural traceries is found in the disposition of the trefoil and quatrefoil, having their symbolic intent of the Trinity and the four Evangelists. And the four Evangelists themselves enter the language of symbolism either as the “four rivers” or Matthew being represented as an angel, Mark as a lion, Luke as a winged ox and John as an eagle. The 12 Apostles were given each their symbol for recognition in art depiction; Saint Peter bearing a key, Saint Jude a cross, Saint Matthew a wallet, Saint Thomas a spear, Saint Simon Zelotes a baton, and so on. At least, from which our science of chemistry arose, was largely a science of mysticism and symbolism. It was probably derived from the Egyptians, not the Arabs as was formerly supposed, and Hermes is, after all, likely to have been the originator.

At first the view evidently was that metals in their changing forms (reactions) had body and soul like human beings, hence lead was called Osiris and considered by the Egyptians as the soul, or “prima materia” of all metals. Later it was supposed that quicksilver (mercury) was the soul of metals. And in the final determining of the alchemists (particularly through the Babylonians) used the planetary names for the metals thus:

<table>
<thead>
<tr>
<th>Planet</th>
<th>Symbol</th>
<th>Metal</th>

</table>

And from the hermetic books sprang our first knowledge of chemistry, in which the chemical contents wrap up in philosophy and religion the search for gold and the philosopher’s stone. And we learn from these students that the stone was “the world in little, microcosm, man: earth; fire; three, mercury, sulphur and salt, or spirit, soul and body.” And we find the alchemists speaking of men as metals and reading such an ancient authority as Issak Hollandus, it is difficult to differentiate between mankind and lead (which is called Saturn), but we are told by his interpreters that he must not be understood to speak of common lead but the lead of the philosophers. Great symbolists were the Rosicrucians, if we may believe what we read about them. From those who claim the origin and existence of the Rosicrucian fraternity as a probable existence of the past we are informed that the writings, ‘Fama’ and ‘Confessio,’ of the early 17th century in mentioning therein the gold which they alchemically created it was “not the gold of the multitude but it is the living gold, the gold of God.” Symbolism, therefore, pure and simple. And later the brotherhood (in England) under Frarius and Fluid transform the ritual into Fice of Death. Its symbolism is stated in the “Summum Bonum.” The Renaissance and Reform arrested the science of symbolism.

The science of heraldry is largely one of symbolism and the numerous crosses have in past days had authorities who deciphered the symbolic intent of their variants, as well as the meaning of many other “charges.” Symbolism has been applied to a language of flowers, as well as to colors, numbers, etc. And each of these fields of application have been more or less adopted by the Christian Church in its symbolism.

The term “symbolism” is used in the technique of psychoanalysis to define a certain brain reflex action, as in dreams, etc. In the method of psychoanalysis there are two spheres or states of the mental process; they are designated the “preconscious” and the “unconscious.” Much of the “unconscious” brain action is what the psyche or unconscious meaning what is known to the lay world primitive or animal. Symbolism in this teaching has a very broad aspect as is disclosed by such an authority as Wm. A. White in the following expression: “For what after all is a word but...
a symbol of an idea and an idea but the symbol of a thing. 9 Whether or not we see the symbolism of a given expression, for example, depends upon the closeness of analogy between the sign and the thing signified. The closer the analogy the less the symbolism and the less easily the symbol grasps the deeper essence of the idea. Symbolism is a mode of expression, the psychological or spiritual thing in the outside world and the word symbolizes the idea. From this point of view our thinking takes place by the use of symbols. 5 In its action, we are told, the symbolism of a word may assume dynamic force (energy). In such dynamic symbol words are included - pride, patriotism, etc. This medical conception and theory of symbolism is claimed to be of assistance in indicating the true inwardness of certain neuroses, as hysteria, etc.

Clement W. Coblue.

SYMBOLISTS, the name of a group of French writers and their imitators in other countries whose school arose in the eighties and at first was supposed to indicate a reaction against Parnassianism and realism. The school or rather style was inaugurated by Philippe Auguste Mathias Villiers de l'Isle-Adam (1838-89) whose play 'Axél' remains the typical drama of the Symbolists. The Symbolists are so called from their habit of introducing an object or being merely as an expression of an idea. Dreams, mythology, music, are their favorite subjects, which they commonly interpret in lyric verse. Form and expression count more with them than substance. Their characters are often degenerate, their themes repulsive, their wit redolent of the gutter and their notions of art rather subservient of morality than otherwise. They were frequently called Décadents, especially the earlier followers of Baudelaire. Jean Moréas (1856-1910) was at first one of the defenders of the principles of the Symbolists and from the apellation of decadent and justifying their innovations as the natural development of the prosody of Baudelaire, Mallarmé and Verlaine. Later he returned to the older forms of versification and to the classical tradition. Other prominent figures among the Symbolists were Gustave Kahn, Catulle Mendès, De Rémé, the Belgians Maeterlinck and Rodenbach, the Americans Vielé-Griffin and Stuart Merrill, the Irishmen John M. Synge and William Butler Yeats and the Englishman Aubrey Beardsley, whose unworthy pictorial productions certainly classify him with the Symbolists. The most beneficial innovation of the Symbolists lay in their attempts to break away from the formalism and stiffness of French versification in their attempts at rhymed prose or vers libre. They abandoned rhyme and the fixed traditional forms and revelled in assonance, repetition and generally attempted to make their lines the visible counterpart of their themes. (See FRENCH LITERATURE). Consult Barre, André, 'Le Symbolisme' (Paris 1911); Gourmont, Rémy de, 'Le livre des masques: portraits symbolistes, gloses et documents sur les écrivains' (Paris 1896); Külling, G., 'Le Symbolisme' (C. v. 1896); Kahn, Gustave, 'Symbolistes et décadents' (ib. 1902); Pellissier, G., 'Etudes de littérature contemporaine' (ib. 1898); Symons, Arthur, 'The Symbolist Movement in Literature' (London 1899).

SYMBOLS, Astronomical, signs or symbols some of them very ancient, which conveniently represent astronomical objects, phases of the moon, etc., and astronomical terms. They are:

**SYMBOLS OF THE HEAVENLY BODIES.**

The asteroids, except the four given here, are represented by a circle with a number, thus, 9, designates Angelina, the sixty-fourth asteroid, in order of discovery.

**LUNAR PHASES.**
- Moon in conjunction, or new.
- Moon in eastern quadrature, or first quarter.
- Moon in opposition, or full.
- Moon in western quadrature, or last quarter.

**SIGNS OF THE ZODIAC.**
- Aries ........... ♈ Libra ........... ☉
- Taurus .......... ♉ Scorpio ......... ♏
- Gemini .......... ♈ Sagittarius ...... ♑
- Cancer .......... ♎ Capricornus ...... ♐
- Leo ............. ♎ Aquarius ......... ♒
- Virgo .......... ♍ Pieces ............. ☊

**PLANETARY POSITIONS.**
- Ascending node .... ♒ Eastern Quadrature ☐
- Descending node .... ♒ Wester Quadrature ☐
- Conjunction ........ ♒ Trine .......... ☐
- Sextile ........... ♒ Opposition .......... ☐
- Quadrature .......... □

**ASTRONOMICAL CONTRACTIONS.**
- Right ascension, R.A. ☉, or α.
- Declination, Dec. or δ.
- North polar distance, N.P.D.

**SYMBOLS, Chemical, letters or symbols used in chemistry to designate the various chemical elements.** They are merely the first letters of the names of these elements (not in every case of their English name); or when the names of two or more elements begin with the same letter, two letters are used as the symbol, one of which is always the first letter of the name of the element. Generally speaking the letters comprising the symbol are taken from the English name of the element; but in some instances, specially in the cases of metals which have been long known, the symbols are derived from the Latin names: thus we have Hg, symbol for mercury, from the Latin Hydrargyrum; Fe, from the Latin Ferrum, for iron; and so on. In a few cases the symbols are deduced from the old German names: thus K, the symbol for potassium, is the first letter of the old German word Kalium, and Na, the symbol for sodium, is from the German Natrum. However derived, whether from English, German, Latin or French, the symbols of the chemical elements are universally the same. For a considerable time French chemists employed the symbol As to represent nitrogen, from the name Azote, which was given to this element in reference to the fact that it alone could not support life (Greek, a, privative, and ze, life); but this symbol is now almost entirely superseded by the letter N. The symbols of chemical compounds are constructed by placing together the symbols of their constituent elements, a number being attached to each signifying how many atoms of the element enter into the composition of the amount of the compound expressed by the entire symbol. For it must be understood that chemical symbols have a quantitative as well as a qualitative meaning. When a chemist meets in a chemical treatise with the symbol O he knows that this signifies not only oxygen but a certain definite amount by weight of oxygen, O always means 16 parts by weight of oxygen, so Fe means 56 parts by weight of iron; and so also the compound symbol FeO₃ means (56 × 2) + (16 × 3) = 160 parts by weight of oxide of iron. For a further account of the uses and modes of formation of chemical symbols see the article CHEMISTRY.

**SYMBOLS, Mathematical, signs or abbreviations used in mathematical operations for the sake of brevity and to facilitate expression.** In arithmetic and algebra there are four general kinds of symbols used; namely, those of quantity, operation, relation and abbreviation. Quantities are generally represented by letters. Known quantities are represented by the leading letters of the alphabet, or by the final letters with one or more accents, thus: \( x', x'', y', \) etc. Unknown quantities are represented by the final letters of the alphabet, as \( x, y, z \), etc. Besides the English letters, those of the Greek alphabet are often made use of. Certain letters have come to represent certain quantities. Thus, \( \pi \) generally stands for the ratio of the diameter to the circumference of circle, or the number 3.1416; \( e \) denotes the base of the Napierian system of logarithms, or the number 2.718281828; \( M \) denotes the modulus of any system of logarithms. The symbol \( \infty \) denotes an infinitely great quantity.

Of the symbols of operation the sign \( + \), plus, when written between two quantities, signifies that the second is to be added to the first; as, \( a + b \). The sign \( - \), minus, when placed between two quantities, denotes that the one on the right is to be subtracted from the one on the left; as, \( a - b \). The sign \( \times \), when placed between two quantities, denotes that the one on the left is to be multiplied by the one on the right; as, \( a \times b \). Multiplication may be indicated by placing a point between the factors when they are both expressed by letters; as, \( a \cdot b \). This method is not applicable when the factors are numbers, because, in that case the indicated product would be confounded with a mixed decimal fraction; thus, 5,6 instead of being read, product of \( \frac{5}{6} \), would be read \( 5 \frac{6}{10} \) and 6-tenths. There are cases, however, where the symbol is used between numerical factors, as in series where the factors follow a law which it is desirable to keep before the eye; thus the general term of the binomial formula is
\[
m(n - 1)(n - 2) \ldots (m - n + 1) = a \cdot x^{m-n}.
\]
The sign \( \div \), placed between two quantities, indicates that the one on the left is to be divided by the one on the right; as, \( a \div b \). Division may also be indicated by writing the quantities in place of the points; as, \( \frac{a}{b} \) or \( a : b \), or \( a/b \), \( a/b \). The sign \( \sim \) denotes the difference between two quantities, without
implying which is to be subtracted from the other; as, \(a \sim b\). The sign \(\sqrt{\cdot}\) is called the radical or evolution sign, and when placed over a quantity indicates that its root is to be taken; as, \(\sqrt{a}\); the degree of the root is indicated by a number written over the sign, which is called the index of the root or radical; thus \(\sqrt[3]{a}\), \(\sqrt[n]{a}\), etc. The sign \(\sqrt[\cdot]{\cdot}\) indicates the square root.

A vinculum (\(\bar{\cdot}\)) bar \(\cdot\) brackets \(\{\cdot\}\), parenthesis \((\cdot)\), etc., indicate that the quantities enclosed by them are to be regarded together; as, \((a+b)\times, a\times b\), etc. The symbol \(\sum\) denotes that \(+\cdot\)

the algebraic sum of several quantities of the same nature as that to which the symbol is prefixed is to be taken, thus,

\[
\sum_{n=0}^{\infty} \frac{q^n}{n!} = \frac{1}{p} \left( e^n - 1 \right)
\]

is a formula, in which \(p\) being constant and \(q\) and \(n\) arbitrary, signifies that the algebraic sum of any number of terms deduced by attributing values to \(q\) and \(n\) is equal to \(\frac{1}{p}\) multiplied by the difference of the algebraic sum of the terms, which are deduced by attributing the same values to \(q\) and \(n\) in the expressions \(\sum\frac{q^n}{n!}\)

and \(\sum\frac{q^n}{n!} = \frac{1}{p}\). Of the symbols of relation \(f, F, \phi, \theta\), written before any quantity, or quantities, separated by commas, as \(F(x), f(x, y), \phi(x, y, z), \theta(x, y, z)\), etc., denotes quantities depending upon the quantity or quantities within the parenthesis, without designating the nature of the relation. The sign of equality, \(=\), between two quantities, denotes that those quantities are equal to each other. The sign of inequality, \(>\), placed between two quantities, denotes that the one placed at the opening of the sign is greater than the one placed at the vertex of the sign; thus, \(a > b\), \(a\) is greater than \(b\); but \(a < b\), \(a\) is less than \(b\); also, \(a \geq b\), \(a\) is not greater than \(b\); \(a \leq b\), \(a\) is not less than \(b\). The sign \(\neq\) is a negation of equality; as, \(a \neq b\), \(a\) is not equal to \(b\). The signs of proportion \(::\), \(\because\), placed between quantities, taken two and two, show that the quantities are in proportion; thus, \(a : b :: c : d\), is read, \(a\) is to \(b\) as \(c\) is to \(d\). The first and third signs are signs of ratio, and the second the sign of equality, so that the above might be written

\[
\frac{b}{a} = \frac{d}{c}
\]

Of the symbols of abbreviation the sign \(\therefore\) stands for therefore or hence and \(\because\) stands for since or because. Other algebraic and mathematical symbols are \(\%\) for per cent or \(\times\) for per thousand; \(\#\) the symbol of integration; the Decinal, as in 5.6 (America), 56 (Great Britain), 56 (Continental Europe), meaning 5 and 6-tenths; identity \(\equiv\).

Geometry borrows most of its symbols from those of algebra just explained. Magnitudes are represented pictorially; the symbols \(\angle \angle\) are pictorial representations of angle, angles. \(\parallel\) means parallel to; \(\perp\) perpendicular to; \(\Delta, A\) represent pictorially the terms triangle and triangles respectively; while \(\odot, \odot\), represent circle, circles; \(\square, \square\), square, squares; \(\equiv\), \(\equiv\), \(\equiv\), represent parallelogram and parallelograms. Arc is represented by the symbol \(\equiv\) and radian; \(\equiv\), \(\equiv\), \(\equiv\), means congruent to and \(\equiv\) similar to. See Notation and consult Cambr., M. B., 'Vorlesungen über Geschichte Mathematik' (Leipzig 1910); 'Vorschule zur Vereinheitlichung der Mathematischen in Schulanstalt,' in 'Schulen des deutschen Ausschusses für den mathematischen und naturwissenschaftlichen Unterricht' (ib. 1913). This contains an extended list of symbols.

SYME, sim., James, Scottish surgeon; b. Edinburgh, 7 Nov. 1799; d. 26 June 1870. He was educated at the university of his native city, and studied anatomy under Barclay and Liston, visiting also Paris and Germany. In 1829 he opened Minto House Hospital, which he carried on for four years with great success as a surgical charity and school of clinical instruction; and in 1833 was appointed professor of clinical surgery in Edinburgh University. In 1847, on Liston's death, he became professor in University College, London; he soon, however, returned to his former chair in Edinburgh, and continued to hold it till his death. Among his numerous writings are a 'Treatise on the Excision of Diseased Joints'; 'Principles of Surgery'; 'Diseases of the Rectum' (1838); 'Pathology and Practice of Surgery' (1848); 'Stricture of the Urethra' (1849). Consult Paterson, R., 'Memorials of the Life of James Syme' (Edinburgh 1874).

SYMEONIS ('SIMMONS'), Henry, the hero of the most persistent and unique feud in history: Oxford University having for nearly 600 years (till 1827) required every candidate for the baccalaureate to swear war, not even against Symeons' posteriority, but against allowing himself, centuries dead, to be 'reconciled.' The only explanation hitherto given in a cyclopædia is an incredibly silly guess of Brian Twyne in 1668, that Symeon had feigned the baccalaureate before attaining it, and that his rite would never have gobbled him for the ages. In fact, the cause was precisely his not being a student at all. He was a wealthy citizen of Oxford, who about 1242, in the first historic sworn and gown row, killed a student and fled into exile from the vengeance of the others. Against their protest Henry III allowed him to compound for £80 (some £5,000 now) and return to stand trial. The university seems to have fought this off for nearly 20 years; and when overborne in 1254, they made this at least one grievance for most of them removing to Northampton. Simon de Montfort on mastering the king in that year recalled them; presumably, therefore, Symeons' permit was rescinded. At all events, the university exacted an oath from all degree men thereafter not to consent to any new baccalaureate — that is, peaceable residence in their town. It was retained after his death in terroriam as a warning to all who might molest Oxford students; and at last mummied as part of a set of historic victorics not to be canceled, though this one was long forgotten.
SYNGTON, William: British engineer and inventor; b. Leadhills, Scotland, 1763; d. London, 22 March, 1831. He was educated at the universities of Edinburgh and Glasgow, studying for the ministry, but abandoned that profession to become a civil engineer. In 1787 he took out a patent for an improved form of steam-engine, and in 1802, after years of futile attempts, he succeeded in propelling the tugboat Charlotte Dundas by means of steam-engines with which he had fitted her. He gained the patronage of the Duke of Bridgewater, but the death of the duke in 1803 left him without the financial support necessary for the promotion of his venture, and being unable to gain it elsewhere, he drifted from place to place, finally dying in poverty.

SYMMACHUS, Pope (498–514): b. Car-dinia (?); d. Rome, 19 July 514. He was baptized at Rome, entered the ranks of the clergy and was ordained deacon. He was elected and consecrated Pope 22 Nov. 498, succeeding Pope Anastasius II. However, a minority of the Church of Byzantine learnings, met on the same day and elected the Roman archbishop Maximianus as Pope, and a bitter dispute ensued. The matter was carried to Theodoric, the Gothic ruler of Italy, who decided in favor of Symmachus as having been elected first and by a majority. The Byzantine party, persisted in its efforts to seat Laurentius, established him in Rome and gained control of seven churches. It brought various charges against Symmachus, but after many sittings and much controversy the Synod reached the momentous decision that the Pope is above him (ecclesiae sacerdos) 505 or 506. The order of the Pope to the ordered Laurentius to surrender the churches held by him and his followers and the dispute came to an end. The remainder of Symmachus' reign was uneventful, except in the way of quiet progress. He formulated rules for the sale of Church property which were of great benefit to the Church; and his name is connected with the building or decoration of various churches in Rome.

SYMMACHUS, Sim'a-kús, Quintus Aurelius, Roman statesman of the 4th century. He was educated in Gaul, and after serving as quaestor and praetor became co-rector of Lucania and Bruttii (365) and consul of Africa (373) and member of the pontifical college. His petition to Gratian, urged on the Senate's behalf, for the restoration of the altar of Victory, proved unavailing (382), as did the ex tant letter addressed by him when prefect of the city (384) to Valentinian. The failure led him to side with the pretender Magnus (387), and for so doing he was impeached of treason, but pardoned and raised to the consulship (391). There remains of his works 10 books of letters and fragments of orations. These are contained in Seeck, ‘Monumenta Germaniae Historica: Auctores Antiquissimi’ (Vol. VI, Ethelbert Dilh., S. Roman Society) (London 1899); Dimsdale, M. S., ‘History of Latin Literature’ (New York 1915).

SYMMES, Sim, John Cleves, American soldier and author; b. Sussex County, N. J., about 1780; d. 1829. In 1802 he entered the United States army as ensign and served through the War of 1812, reaching the rank of captain in 1813. At Niagara and the Fort Erie sortie he won distinction. After the war he lived at New York, and in 1822 published a work propounding his own planetary theory, which comprised the belief that planetary bodies, including the earth, consist of hollow concentric spheres open at their poles. The inside of the earth he believed to be inhabited, and he imagined an aperture (known since as ‘Symmes' Hole’) in the earth's crust, near latitude 82° N., communicating with the interior of the planet, where he fancied plant and animal life to exist, and which he described as being lighted with two subterranean suns, Pluto and Proserpine. Humboldt stated that he and Davy had repeatedly been invited by Symmes to descend through this hole to the earth's interior. In 1822 and in 1823 Symmes petitioned Congress for an expedition to test his theory. Jules Verne is said to have made this idea the basis for his story, A Journey to the Centre of the Earth. Symmes advocated his views in lectures and pamphlets, and in a work entitled ‘Theory of Concentric Spheres’ (1826), Consul Atlantic Mankind (April 1873, Symmes' Theory of the Earth).

SYMMES' HOLE. See Symmes, John Cleves.

SYMMETRY. From the Latin symmetria; proportion, symmetry; which, in turn was derived from the Greek symmetria, meaning agreement in dimensions, proportionate. In its present-day intent the word symmetry in the language of the laity can be defined as harmony or balance in the proportions of parts as to the whole.

In geometry.—Two points are said to be symmetrical with respect to a straight line, when the straight line bisects at right angles the straight line joining the two points. Thus in Fig. 1 the two points $P$ and $P'$ are symmetrical with respect to the line $MN$, if $MN$ bisects $PP'$ at right angles. In such a case the line $MN$ is termed the axis of symmetry. Two figures are said to be symmetrical with respect to an axis when every point in one figure has its symmetrical point in the other. Thus in Fig. 2 the figures $ABC$ and $A'B'C'$ are symmetrical with respect to the axis $MN$, if every point in the figure $ABC$ has a symmetrical point in $A'B'C'$ with respect to the median line $MN$. When figures are symmetrical with respect to an axis, by revolving either about the axis and superimposing one over the other, they will be found equal and similar. Two points are said to be symmetrical to a third point, when this third point bisects the straight line joining the two points. Thus in Fig. 3, $P$ and $P'$ are symmetrical with respect to $A$, if the straight line $PP'$ is bisected at $A$. And the point $A$ is called the
centre of symmetry. Two figures are said to be symmetrical with respect to a centre, when as in Fig. 4, the triangles \( A \, B \, C, \, A' \, B' \, C' \) are symmetrical to the centre \( O \), and every point in the triangle \( A \, B \, C \) has a symmetrical point in \( A' \, B' \, C' \). A figure is symmetrical with respect to an axis when it can be divided by that axis into two figures symmetrical with respect to the axis. And a figure is said to be symmetrical with respect to a centre when every straight line drawn through that centre cuts the figure in two points symmetrical with respect to this centre. In solid geometry when two planes intersect they are said to form a die
dral angle. When three or more planes meet in a common point, they are said to form a poly
dedral angle at that point. Two polyed
dal angles are symmetrical, when the face and
dielral angles of one are equal to the face
dielral angles of the other each to each,
but arranged in reverse order. As example
the tri
dedral angles \( S \, A \, B \, C \) and \( S' \, A' \, B' \, C' \)
in Fig 5) are symmetrical when the face-angles

In algebra a function of several quan
tities which is not changed when any two of the
quantities are interchanged, such as \( \alpha \, \beta \), is
called a symmetric function of the quantities.
Such a function of the root of the equation
has been designated by enclosing the exponents
in brackets, expressing the repetition of a num
ber by an exponent: thus \( \alpha^a, \, \beta^b, \, \gamma^c \) — \( a, \, b, \, c \)
is written \( \{ \alpha^a, \, \beta^b, \, \gamma^c \} \). In particular, a symmetric
function of the form \( \{ \alpha \, \beta \, \gamma \} \) = \( \alpha^a + \beta^b + \gamma^c \)
is called an elementary function (Decker).

Physiology.—In the science of biology ani
mals are distinguished as Radially symmetri
cal; bilaterally symmetrical; serially symmetri
cal; assymmetrical. This is a division ac
gording to their structure internally and ex
ternally. In a radially symmetrical animal
such as a jelly-fish, the body can be halved by
a number of vertical planes — it is symmetrical
around the median vertical axis. In other
words it is of the same conformation all round
and possessing neither right nor left.

Symmetrical spherical triangles are those in
which the sides and angles of the one are
equal respectively to the sides and angles of the
other, but arranged in the reverse order. Thus
the spherical triangles \( A \, B \, C \) and \( A' \, B' \, C' \)
(Fig. 6) are symmetrical when the vertices of

the one are at the ends of the diameters from
the vertices of the other (antipodal). Two
symmetrical triangles are mutually equilateral
and equiangular; yet in general they cannot be
made to coincide.

In crystallography which deals with the angular
construction of crystals. The faces or outer sur
faces of crystals are arranged according to
certain laws of symmetry and, based on these
natural laws of symmetry, crystals are divided
into groups and systems. As in geometry, the
relationships of the planes to one another are brought under the heads of the **plane of symmetry**, the axis of symmetry, and the **centre of symmetry**. All may be combined in the same crystal, some have neither characteristic. Study of the conditions has brought the conclusion that there are 32 natural groups among crystals based upon their symmetry. As to *planes of symmetry*, these occur when for each face, edge or solid angle there is another similar face, edge or angle which has a like position with reference to this plane. Thus in a crystal of amphibole it is symmetrical with reference to a central plane of symmetry and, in ideal cases, it is called the **right symmetry**, having for every point on one side of the plane of symmetry its corresponding point at equal distance on the other side. Each half is a **mirror image** of the other half. In some crystals may be found as many as nine planes of symmetry, three of one set and six of another. This is exhibited in the cube. As to **axes of symmetry**, these occur in crystals when, as in geometry, a solid can be rotated through a certain number of degrees about some line as a result of reflection in a plane at a precise angle to itself or reflection in a plane at a precise angle to itself and at a plane parallel to it. The crystal remains itself in a complete revolution of 360°. Thus the axes are **binary**, **trigonal**, **tetragonal**, etc. As to the **centre of symmetry**, most crystals have besides planes and axes of symmetry or without either, a symmetry with reference to a point, its **centre**, as in the triclinic crystal in which every face, edge and solid angle in one half has a face, edge and solid angle in the other half. In such crystal the geometrical conditions we termed **compound symmetry** with reference to axes of binary symmetry and a plane normal to it, if the crystal is calculated as divided into two similar halves by a plane parallel to any one of its faces and one half be rotated 180° about an axis normal to this face. Crystallography exhibits **pseudosymmetry** when their angles apparently approximate in symmetry to the requirements of a system higher in symmetry than that to which in fact they belong. The micas show this tendency, being truly monoclinic in crystallization yet it is believed, at times, rhombohedral or orthorhombic. Grouping crystals according to their symmetrical forms crystallography creates the following divisions: Isometric system; tetragonal system, hexagonal system, orthohombic system, monoscopic system and triclinic system. See **CRYSTALLOGRAPHY.**

**Symmetry in Art.**—In this subject, as in all art matters, we have to go back to the classic Greeks, from whom, as we have seen, the word symmetry itself is derived. And in art circles for numerous generations the term has been the subject of much controversy, hence, according to the evidence introduced and the strength of the theory advanced, the intent of the word among art experts has changed from period to period. As Viollet-le-Duc says, it is used to mean 'precise relation between the measurements, harmony, moderated relations, calculated, in view of resulting satisfaction for the mind and eyes. . . . Symmetry to-day says, in the language of architects, not a ponderation, harmonious relations of the parts of a whole, but a similarity of the opposed parts, the exact reproduction on the right side of an axis of that on the left.' The Roman architect Vitruvius (1st century A.D.) wrote: As to symmetry it is a proper accord of the members, of works among one another, and of separated parts, the relation of each of the parts with the whole, . . . . Vitruvius defines the Greek *symmetras* as "qualitas eurythmiae." But eurythmy means harmony, just proportion, more precisely "correct rhythm." This is the Greek sense of the word *symmetria*, but the great superiority of Greek over all other art has been claimed to be the artists' subjection to symmetry through the *modulus* used as a yard-stick. On doubt, both in their architecture and sculpture, induces a *system*, for comparative measurements absolutely prove this, but, as Viollet-le-Duc claims, the Greeks had no idea of symmetry as "a kind of decalcomania or counterpart"; theirs was altogether a different idea. It was "a harmony of similarity and dissimilarity of parts." Their symmetry was "a relation between established measurements and adopted rhythm." In architecture of great public edifices in which the Greek classic orders figure there is generally a *centre of symmetry* found, as a bisector from the apex of the pediment of the temple forms, or an axis of symmetry revolving around the centre of the boss above the roof of the choragic monument of Lysikrates, etc. The decorative features must, therefore, in harmony follow the similar restricted spaces framed in the right and left ends by the angles of the pediment, by opposed recurrent figures or other triangular designs. But these Attic artists and sculptors showed a freedom from mathematical preciseness that pleases and rests the eye while leaving an appearance of the closest exactitude to measure. Treated from the aesthetic viewpoint, symmetry of geometrical accuracy in art palls on the senses and, with our modern love of freedom and revolution against art, has given rise to the periods in art fluctuating from the stern lines of classic masters and taking flights into fantastic opposed methods as in the case of the rococo style or the baroque orgy of unfettered freedom and degraded license and symmetry thrown to the winds. Symmetry is imposed on the designer of wall papers; landscapes (at times), and gardens to this day show tendencies to symmetry imitative of Dutch method of treatment of past days. And in interior decor and furniture arrangement we find the idea of symmetry prevalent, chairs and other seats as well as mantle ornaments being in sets. Lovers of unrammed art look to the Far East, and especially Japan, for the breach from symmetry in art. There we find symmetrical arrangement, outside of that necessitated in architecture, altogether absent. In the realm of Occidental painting we find the great masters freely grouping their personages in genre work, though in religious work the main figure (we had almost said the "central figure") is liable to appear in the rather exact middle, and the surrounding figures are apt to be divided about equally on either side, giving
SYMONDS — SYMPATHY

symmetrical balance, probably a habit formed through the many years in which such depiction was arranged to cover spaces in churches. To such an extent would modern art have a dubious place in art, outside of architecture, according to recent ideas. The asymmetric art methods of the Japanese have produced a powerful reaction in our Western aesthetic taste and the severities of geometric proportion in art design have lost their hold on the minds of this century's artists and patrons. The conception that symmetrical balance smacks of patterns quite popularly prevails and recent schools are revolutionary in accord with the times.

CLEMENT W. COUMBE.

SYMONDS, sim'onz, Arthur, English poet and critic. b. Milford Haven, Wales, 28 Feb. 1865. He has written an Introduction to the Study of Browning (1886); 'Days and Nights' (1888); 'Silhouettes' (1892); 'London Nights' (1895); 'Studies in Two Literatures' (1897); 'The Symbolist Movement in Literature' (1899); 'Collected Poems' (1901); 'Cities of Italy' (1907); 'The Romantic Movement in English Poetry' (1909); 'Knave of Hearts' (1913); 'Figures of Several Centuries' (1915); 'Tragedies' (1916); 'Tristan and Iseult' (1917). He has edited the essays of Leigh Hunt, the plays of Shakespeare, etc.

SYMONDS, George Gardner, American artist: b. Chicago, 1865. He received early training at the Art Institute, Chicago, and at Paris, Munich and London. His work was awarded numerous medals and prizes, and he was elected National Academician in 1900. He has been represented by 'The Quiescent River' in the Metropolitan Museum, New York City; 'Sorrow' in the Cincinnati Museum; 'Snow Clouds' in the Corcoran Gallery, Washington, and 'The Winter Sun' in the Art Institute, Chicago.

SYMPATHETIC STRIKE. See STRIKES AND LOCKOUTS.

SYMPATHY, is in itself feeling felt, and became possible only after human reason began its operations. As feeling, its discussion belongs to psychology; as a sociogenetic power, its consideration is sociological; as a "motive principle of judgment" (Hoffding), it is the concern of the moralist. In any article such as this, it is almost unavoidable to discuss the subject, without at one and the same time involving all three approaches to the consideration of the meaning of sympathy and here no attempt will be made to avoid such a union. As feeling, sympathy is a secondary, it is a representative pain. It is an echo in one's self of the pains of others. Hedonism of all forms makes unconscious conceptions of the subject; and some separation in the brilliancy of individual passages. Other volumes in this general field are 'An Introduction to the Study of Dante' (1872); 'Shakespeare's Prefaces in the English Drama' (1884), an excellent contribution to the history of English literature; lives of Sidney (1887) and Jonson (1887) in the 'English Men of Letters' series, of Michelangelo (1893) and Boccaccio (1895); and English renderings of the 'Novels of Michelangelo and Campanella' (1878) and the 'Autobiography of Benvenuto Cellini' (1888). Others of Symonds' works are 'Studies of the Greek Poets' (1874-75), designed for the popular reader and approaching Hellenic literature through the individuality of the authors; 'Sketches in Italy and Greece' (1874); 'Sketches and Studies in Italy' (1879); 'Essays, Speculative and Descriptive' (1880); 'In the Key of' 'Essay' (1881); 'The Art of Whitmore' (1884); and 'The Books of Memory' (1884); 'Now and Old' (1889), and 'Vagabunduli Libellii: a collection of sonnets' (1881). Symonds' critical work is marked by a finished style and a distinctive note of liberal culture. Consult the 'Life' prepared from correspondence by H. F. Brown (1895); "Herbert Warren's 'Cortwright's History of the Century'; Brooks, V.; 'J. A. Symonds: A Biographical Study' (New York 1914).
ight be an idle speculation to attempt to
in the very earliest form of sympathy.

experienced by a highly rational being,
not (not its blossom), which is sympathy.
doctor of a high rational power of intel-
activity capable not only of representing
the painful states of others, but also of
necing the reflex of such representations
self as a form of pain. For it requires
or bulk, and it is thus difficult for the
other, to represent to one’s self the pains
rs. When once such power is acquired,
is a reflex of the represented pain to self’s reflected pain felt by one representing
not the external stimuli. The reluc-
tude becomes more vivid, he general organization of a human being
more delicate and more refined. Such
gree of differentiation was, one may be
in being attained at an early stage
an development, a fact, which, it may be
mentioned, explains such vicious and abnormal
institutions as the savage subjection of women.
Civilization has been, and may indeed be,
measured by the capacity of men for suffering
representative pain or sympathy and by their
efforts to relieve it. For in the merely animal
kingdom it may be suspected that there is
scarcely any, if there is any, sympathy with
suffering at all. And yet as the fine painting
by Landseer of a 9th Monkeys illustrates,
one may well hesitate to pronounce that feel-
ings of sympathy are entirely alien to the animal
world.

SYMPHONY, an elaborate musical compo-
position for a full orchestra, consisting usually,
like the sonata, of three or four contrasted yet
inwardly related movements, as an andante fol-
lowed by an allegro, another andante varied or
an adagio, a minuet with its trio or a scherzo,
the whole composition closing with a lively
rondo or rapid finale. The symphony, which
may be regarded as the highest kind of musical
composition, was unknown in its present form
before the time of Haydn, who with Mozart,
Mendelssohn and Beethoven are the most suc-
cessful composers of this class of compositions.
The nine symphonies of the latter are gener-
ally recognized as being the noblest works of their
kind. The term symphony is also frequently
applied to short introductory or closing instru-
mental passages in compositions which are
predominantly vocal. See Music; Orchestra.

SYMPTOMOMETER, a kind of barometer
in which the weight of the air is indicated by
the compression of gas in a tube, the lower
part of the tube being filled with some oily fluid
and the gas occupying the upper portion.

SYMPOSIUM, The. In the Symposium
Plato tells the story (in the main fictitious, no
doubt) of a banquet given by Agathon in cele-
boration of a tragic victory on the stage. In-
stead of the usual diversions over their cups
the guests propose to entertain themselves with
successive encomiums of Eros, the god of love;
and of these speeches is formed the bulk
of the dialogue. The most noted section is that
put into the mouth of Aristophanes, the comedian, in which occurs the
humorously worded (not without deep significance)
of the creation of man as a rounded whole,
with four arms, four legs, etc., and of his slic-
ing afterward by Zeus into two half-beings,
male and female, who are driven by love to
endeavor to reunite themselves once again into
a perfect whole. When called upon last, Soc-
rates, with his customary irony, protests his
ignorance, but consents to regale the company
with a tale he pretends to have heard from
a certain wise woman of Mantinea. According
to this prophetess, Eros is the offspring of the
god Poros ("Plenty") and the mortal Penia
("Poverty"); he is thus not properly a god, but
a mighty daemon, or intermediary being, whose
office it is to form a link between the eternal
bounty of heaven and the conscious imperfec-
tion of mankind. Love, the allegory would say,
is not the happiness of the sexes — happiness belongs only to the gods—but the
unsatiated longing to possess. By its creative
power it is man’s substitute for immortality;
for if the individual must perish, yet he is per-
mitted by love to continue his existence in his
children. It is the source of art, leading men
to satisfy by the creation of beautiful forms their innate longing for the absolute beauty that excites them. It is the cause of philosophy. He is not a philosopher, but a god, who knows the truth; nor is he a philosopher who is unaware of his ignorance; rather, the philosopher is he, who, being aware of his ignorance, is driven on ever by the soul's thirst for the truth, to learn and to raise his life into one continual communion with the world of ideas. Whether later in date of composition or not, the 'Symposium' is logically a sequel to the mythological portions of the 'Phaedrus.' In the earlier dialogue Socrates tells how in some remote age the soul of man, in its winged chariot, followed the procession of the gods to the summit of the celestial vault, and from there beheld the everlasting ideas of truth and justice and beauty and the like, of which things true and just and beautiful in this world are the shadowy transient images. And so, when a man sees some fair object or person, love is awakened in his soul as a reminiscence of that half-forgotten vision. In the 'Symposium' the musical nature of love as a reminiscence is less emphasized, but its dynamic and philosophic function is developed in splendid imagery. Without this emotional quality, as it is worked out here and as it is suggested in other dialogues, the ideas of Plato would be a curious theme for the metaphysician; with the introduction of love as the force driving us to participation in their divine nature, the philosophy of Plato is transformed into something that has enthralled poets and artists and entered largely into the rapture of the saints; it has become one of the molding influences of civilization. But it cannot be said that this influence has been entirely for good. From this source has come the popular notion of "Platonic love," which has acted as a befuddling and enervating ferment in society. It is fair to add that Platonic love, as most of the poets have understood it, is the very reverse of what Plato himself had in mind. Petrarch, for instance, would absorb the universe into his passion for a woman; Plato would forget the woman in his pursuit of ideal beauty. It is right to remember also that the conclusion of the 'Symposium' contains the extraordinary confession of Alcibiades, in which, as if Plato was concerned to remove any misunderstanding of his doctrine, Socrates is pictured as the stalwart soldier and as a lover, proof against every seduction of the flesh, a man of iron character above all. Nevertheless Plato's language, when dealing with the passion of beauty, is sometimes unguarded. The 'Symposium' is commonly regarded as Plato's most perfect literary production, as perhaps the most perfect piece of prose composition of any age or in any tongue.

Paul Elmer More

SYMPTOMS, in medicine, the phenomena from which are inferred the existence and nature of disease. Symptoms have their seat in the functions which are affected by the disease, so as to be raised above their usual activity, or depressed below it, or even to be changed in the nature of their action. The organs themselves are often changed in their appearance, structure, size, etc. Symptoms may be perceptible by the patient alone (for example, pain and all change of sensations), or by the physician also (for example, all diseased movements). The nervous, the vascular and the cutaneous systems, for instance, are affected in most diseases; hence also irritability, the power of nutrition, etc., which extend through the whole organization, are so easily affected by diseases, and thus afford symptoms. If the latter are in the organs originally affected they are called idiosyncratic; but if they are caused by sympathy with other and distant parts, they are called consensual or sympathetic. The temperament, age, sex, mode of living, etc., of the patient produce a considerable variety in the symptoms of every disease. When they are indubitable signs of a particular disease, symptoms are called pathognomonic.

SYNAGOGUE. See JEWS AND JUDAISM.

SYNAPTA, a genus of a group of holothurians distinguished by the non-development of an ambulacral system. Locomotion in Synapta is effected by the muscular contractions of the body, aided by the presence in the skin of anchor-shaped spicules of lime, which these animals use to fix one portion of the body, while the other portion is pulled forward. These animals live in muddy coasts and form mud-cases. See Holothuria.

SYNCHRONIZER, an instrument in common use in electric-generating stations employed to indicate the relation between the frequency of two or more alternating current generators and especially to show when a generator is operating at the same frequency as others with which it is the desire of the engineer to connect it, in the same circuit. A variety of the instrument is also employed to determine when the voltages of two circuits are in phase with each other. A common form of the instrument is a small motor the armature of which is connected to one generator and the field-windings to another. By an arrangement of armature coils a rotating field is produced which turns the armature in one direction or the other according to the difference in phase between the circuits. A pointer turned by this shows which generator is fast and which slow. Another form consists of two incandescent lamps connected in the two circuits in such a manner that they light up or remain dark when circuit is closed. Consult Jansky, C. M., 'Electrical Meters' (New York 1912) and Edgcumbe, K. W. E., 'Industrial Electrical Measuring Instruments' (ib. 1908).

SYNCHRONOGRAPH. See TELEGRAPH.

SYNCHRONOUS MOTOR. See ELECTRICAL TERMS.

SYNCLINE. See Fold.

SYNCLINORIUM. See Fold.

SYNCOPE. See FAINT.

SYNCRETISTIC CONTROVERSY. The name given in church history to the disputes which attended prolonged and repeated efforts in the 17th century to bring about the union of all Protestant churches. George Calixtus, pro-
theology at Helmstadt, was the author of an opposition, which was brought forward from 1645 to 1686, when the discussion finally abandoned. See LUTHERANISM.

SYDIC, (1) in government and commerce, officer in various countries entrusted with affairs of a city or other community, of art or trade, etc., who calls meetings, represents, etc. (2) Also a permitted to act in some particular affair he has a common interest with his con-

SYDICALISM, a political and industrial which demands that the means of production and distribution in government shall be open to all those workers who are able and necessary in the community, to many different views on the subject, the belief in cooperation and equality, but a general description is aimed at being antagonistic to every other form of government, whether by government, existing orders or by capital. The motivating force of syndicalism is to form the enthusiasm of the workers. It distrusts organization, delegates arms of leadership except that of the force, Force is the basis of society, weapon is to reform the world. The main aim is to eliminate the present production. The means to accomplish the theories of different exponent doctrine, but they may be generally here. Sabotage, boycotting, strikes and disturbances of all kinds are legitimate, and to avert the possibility of armed force being used to accomplish this, then use their ultimate name. This demands the general strike. This demands the general strike. This demands the action of the entire movement, which, armed, will be compelled to the working class. This having been done, they finally propose to abolish and master; level the reward of all differences of production and education, and trade unions and local organizations. It differs from socialism in that the social revolution through means to abolish capital; whereas the latter to work reform through political means, by gaining majority in existing government. Furthermore, Socialism aims at full participation of the government control and rich unions with capable leaders; syndicalism prefers poor unions and an aura of authority. It differs from the movement in that in its constructive aims at decentralization of trade stead of one tremendous all-embracing organization. The movement began in 1892, when the European were 600,000 avowed Syndicalists. Since it spread to Italy where it was most actively by the agriculturists who at that time were organized and able on the co-operative plan; and the Iway system was under the influence of the movement.

The movement has a large following in England, some 60,000 being present at a conference held before the war. An American similar movement began under the direction of the I. W. W. Russia has many different classes of labor agitators,—the Bolsheviks embody many Syndicalist principles. Traces of it are found also in Spain, Greece and Latin America. Consult Brooks, 'Syndicalism' (1913); MacDonald, 'Syndicalist' (1913); Lewis, A. D., 'Syndicalism and the General Strike' (Boston 1912); Clay, Sir Arthur, 'Syndicalism and Labor' (London 1911); Challaye, F., 'Syndicalisme revolutionnaire et syndicalisme dans l'evolution sociale' (Paris 1908); Harley, J. H., 'Syndicalism and the Labor Unrest' (in the Contemporary Review, March 1912); Kleinlein, Andreas, 'Der Syndikalismus in Deutschland' (Brussels 1912); Lanzillo, A., 'Le movement ouvrier en Italie' (Paris n. d.), and the works of Georges Sorel.

SYNDICATES, a name given in the United States to those combinations of capitalists organized for the purpose of controlling production and raising prices. The term is also used of associations which buy a literary or artistic product outright from the author and market it to subscribers simultaneously in non-contiguous parts of the country. Perhaps the most familiar example of this is the colored SundaySupplements which appear in different journals on the same day at points throughout the continent from the Atlantic to the Pacific.

SYNDROMES, Endocrinous. The conceptions concerning the push that lies behind the metabolism of the human body even in recent years have been all too elementary and simplistic. They have, however, slowly and gradually undergone modification until the importance of a number of overlooked structures have forced themselves within the past 10 years (1910-20) almost with a rush upon the medical horizon. These structures are the endocrine glands or the hormonopoietic system. Their study now constitutes an enormous specialty.

As early as 1838 Parry called attention to the relationship between enlarged thyroid and rapid heart beat, since which time the works of J ohannes Muller, Addison, Gull, Brown-Séquard, Marie and many others have served as starting points for the building up of a rich structure which is amply recorded in a score of monographs. The chief of these are Biedl, 'Internal Secretions' (bibliography of 4,000 titles, 1913); Falta, 'Ductless Glands' (1915); Parhon et Golstein, 'Les Secretions Internes' (1909); Levy and Rothschild, 'Endocrinologie' (1913); Gley, 'Les Secretions Internes' (1914); Sa joux, 'Internal Secretions'; Pende, 'Endocrinologia,' and the special articles in Lewandowski's 'Handbuch der Neurologie' (1913). In addition to these a large number of special monographs upon the individual structures have been written all of which may be found in the works here quoted in the Bibliography.

• Out of this prodigious development, much of which is evanescent and hastily constructed, a large amount of solid substance remains and a number of permanent acquisitions have been made. The net result has been to show much more essentially than ever before the funda-
mental physicochemical foundations of biological metabolic processes as they are utilized in the upkeep of the animal machine. The viewpoint has been advanced that the chemical interrelationships take place between the different organs of the body. That this is automatically regulated through the vegetative nervous system (the old sympathetic) chiefly, apparently in some cases, though this is by no means clear, solely through chemical regulation. The disorders of this adjustment now constitute a special department of vegetative neurology, and are most conveniently grouped under the term endocrinology, or the endocrinopathies.

In the earlier period of the study of these endocrinopathies individual disease groups, uniglandular syndromes, were isolated. Among the most accentuated of these were Addison's disease, diabetes mellitus, myxedema, erythema and acromegaly, but of recent years it has been increasingly emphasized that whereas a certain group of symptoms, which may be linked to plus or minus activities of one or another gland may be at times present, other glandular modifications are bound up in them and are not to be neglected. Hence has arisen the viewpoint that most of the endocrinopathies are, strictly speaking, poly- or pluri-glandular syndromes.

In many years, even back to the earliest days of primitive animistic magic, it has been held that every living tissue yields a chemical product which will act upon other tissues. The early alchemistic studies, those of Paracelsus, to the latter work of Halhmann, and the isotherapists, are all attempts to co-ordinate a host of empirically observed facts. They are all worth rereading if the reader will put himself in sympathy with them through a comprehension of the laws strange symbols then used.

Endocrin glands for the present purposes are those structures which yield products termed hormones and chalone having some definite or specific action related to, yet different from, enzyme activities. These structures are developed from different embryological formations: The hypophysis (posterior lobe) and chromaffin tissues (suprarenal chiefly) are nervous; the thyroid and pituitary (anterior lobe) come from the buccal cavity; the pancreas and mucosa of the small intestine from the branchio, the parathyroids and thymus from the branchial arches (old slit slits of fish); the gonads (testes and ovary) and the intra-renal bodies from the genital ridges. Some of these, in humans, merge into one structure, as thyroid and parathyroid, as chromal and thymus in the suprarenal, as hypophysis (posterior lobe) and pituitary (anterior lobe).

The present article will attempt to sketch only the general outlines of the various uniglandular and pluri-glandular syndromes. The more radical French school is followed, but at the same time attention should be called to the fact that the French school presentations contain some fallacies, and should be read with caution. Still the clinical suggestions of these works are so rich that they need to be a matter of constant to call the attention of the physician to possible relationships rather than to take the more conservative attitude of directing attention only to that which can be indubitably proved. This whole subject is still so empirical that the principle of putting hypotheses to a test will be found to be advantageous than of believing too obviously. The former attitude never gaining useful therapeutic truths, comes monotonous and frequently seems stupidly.

The more recent suggestive and summaries of Biedl, Falta, Laigmel, Levi and Rothschild are therefore maritized.

Uniglandular Syndromes.—Thyroid Myxedema.—The chief symptoms are: development, dwarfism, infantilism, it of skin and mucous membranes, mental slow ideation, defective memory, apathy, slowness, sleepiness, taciturn, iness. The pulse is usually small, rapid, and regular, at times morbidly increased. The constipation, diminished urination, hypo- or hypothyroidism, chininess of the skin. Reflexes dimin The voice is often nasal, slow, monotonous and raucous. Headache is frequent at times epileptic. Other glandular symptoms of diminished secretion.

Exophthalmic Goitre.—A more or less complete catalogue of findings for a lot of case include tachycardia, arrhythmia, anxiety, tions in the neck, exophthalmos, epiphysis Graef's, Stellwag's, Mabius' symptoms, paresis, cramps, tremors, neuralgias, frontal and ocular, colic, hot flashes, sweats, thermophobia, engorgement of dermographism, transitory edemas, palpitation, uticaria, alopecia, diminution of el resistance, albuminuria, polyuria or glycosuria, bulimia, vomiting, ptyalism, chlorhydria, diarrhea, dyspepsia, atrophy of mammary, loss of flesh, emotional instability, volubility, in- anxiety, excessive anger or reverse, excitement, marked depression, cyclic variations, confusion, epileptic attacks finger and Hess have endeavored to a vagotonic and sympathicotonic type.

In the vagotonic type the more pre signs are decreased lacrimation, less e mos, with enlargement of the parotid v. Graef's sign, abundant sweating, mild tachycardia, no alimentary glycopenia and oculocardiac reflexes possible. The sympathicotonic types there are cases. Dryness of eyes, violent tactile glycosuria, oculocardiac reflex reversed sent, increased reaction to adrenalin. cases are mixed in type. In all save infants psychical influence are strict psychotherapy is extremely valuable in stages, less so in chronic cases. Mor bulk large in the etiology of the psy cases.

Thyroid insufficiencies, other than myxedema, are infantilism, obesity, syndromes, pseudolipomatosi s, alopecia, pre loss of hair, celeroderma, urticaria, prur itu reigning herps, transitory edemas, in a vasm, coaptation, mucous enter dactylopathy, acne, erythema, rhinorrhea, glucose toler ance, chilliness, mammary h.

Thyroid Instability (Levi and Rot From dyshypothyroidism: chilliness, b
depression, crying, giddiness, passing
neuralgic pains, suffocations, shivering,
et al menstrual period. With pre-
dysthyroidism: the following symp-
ms: tear secretion, hot flashes, a
intestinal spasms, irritability, emo-
phobias, inquietudes, migraine, asthma,
asis dysdiastasis, tremors. Mixed cases:
shivering, migraine, frequent urin-
ation, pain, reddening of
, catamenia; neuralgia, anxiety, dilata-
tion of visceral, swelling of feet, varia-
volume of the feet, tremors, nervous
sterical attacks.

byroid.—Tetany.—This syndrome is
ably related to parathyroid loss or de-
akinson's syndrome(?). The view
Lundborg and of Gauthier is that this
belongs here, and is a hyperfunction
but it rests on very unstable founda-
ms.—Vagotonic Symptoms of Basedow
(?): Profuse sweating, palpitation,
osis, eosinophilia, sensation of weak-
thenia of Erb-Goldflam (?): Headache,
ternal ophthalmoplegia, fixed or transi-
tis principally of the face, the neck, ic
ic electrical reaction.
: Loss: Idiocy of Klose and Vogt.
?: Basch.
renals.—Addison's Syndrome and Sup-
sufficiency: Asthenia, arterial hyperten-
sion, nausea and vomiting, lumbar
lanoderma, white lines on the skin,
ny, abulia, depression. At times
ic, epileptic attacks, tetany, periodic delirium, mental confusion, sudden
renal-genital Syndrome: External femi-
udo-hermaproditism with virile sec-
osexual characters; suprarenal virilism;
hea, gynecostasy, adiposis with easy
all signs of feminine maturity; hy-
y of the clitoris, hypertrichosis of e
type, masculine voice, muscular and
hypertension, active and violent sexual
; arterial hypertension, arteriosclerosis.
atic Parangalia.—Chromaffin cells
olar plexus, aortic parangion of andi,
cardiac parangion of Wiesel
ner, Luschka's carotid and coccygeal
tympanic parangalia. The syndrome
ctions of these glands is entirely
reas.—Diabetes Mellitus: Glycosuria,
polyphagia, polydipsia; neuralgias,
impotency, constipation, dry mouth,
diminished perspiration, atrophy of
icles, abolition of the tendon reflexes,
hypertension, asthenia, headache, sus-
y to cold, perforating ulcer of the foot,
s, comatose or apoplectic attacks,
, vertigos, asthmatic dyspnea, pseudo-
marcolysis, depression, apathy, hypo-
and coma.
ophys.—Froehlich's Genital Adiposity
ne: Adiposity, arrest of development or
of the genital glands, of the genital
nd the corresponding secondary sexual
smolence.
rome of Hypophyseal Insufficiency of
Renon and Delille: Tachycardia, instability of
the pulse, arterial hypotension, insomnia, an-
orexia, distressing sensation of heat, exaggera-
tion of sweat secretion in
eyebrow development, hot flashes, a
intestinal spasms, irritability, emo-
phobias, inquietudes, migraine, asthma,
asis dysdiastasis, tremors. Mixed cases:
shivering, migraine, frequent urin-
ation, pain, reddening of
, catamenia; neuralgia, anxiety, dilata-
tion of visceral, swelling of feet, varia-
volume of the feet, tremors, nervous
sterical attacks.

Synergism — Syngye

Surnareal Predominance.—Addisonian with

amnenorrhoea, impotence, chilliness, tetany or, on

the other hand, exophthalmic goitre.

Very often Baseadovian, acromegalics,

giants, with spontaneous glycousia, alimentary

or merely adrenal, the latter making it possible

in certain cases to suppose a certain degree of

suprarenal hyperactivity.

Without Marked Predominance.—The case

of Claude and Gougerot is an example: Loss

of sexual characters, countenance old-looking

skin thickened, wrinkled, pigmented; chilliness;

absence of perspiration, asthenia, arterial hypo-

tension, tetany; resticcular, prostatic, suprarenal,

thyroidal and perhaps parathyroidal atrophy.

Consult Jalilhe and White, 'Diseases of the

Nervous System' (3d ed., 1919; chap. III, 'The

Endocrinopathies')

Smith Ely Jelliffe, M.D.

Synergism, the co-operation of man

with God in the act of his conversion; the term

was first employed to designate the relation of

man to the Holy Spirit in the work of conver-

sion, as defined by Melanchthon in the 'Let-

terum' (1548). Luther, in his commentary on

Genesis, allows to man no part whatever in this act: "In things spiritual and divine which

are to the salvation of the soul, man is like

the pillar of salt into which Lot's wife was

transformed; nay he is like to a block and a

stone, a lifeless statue which has no use of

eyes, mouth, of any of the senses, or of the

heart." Melanchthon's doctrine (which, how-

ever, he soon retracted) was that "God does

not deal with man as with a block, but draws

him so that his will co-operates"; it was a

term of co-operation that gave to Melan-

cthon's doctrine the title Synergism.

studied in Alexandria, where he was the friend

and pupil of Hypatia (q.v.). In 409 he was

baptized in the Christian Church and the fol-

lowing year consecrated bishop of Ptolemisii

in North Africa. He published his philosophical

works and completed his religious writings, in

his works: homilies, letters, hymns and other

literary works. In these exhibits multitudinous learning, keenness of

intellect and a glowing style. The Christian

domains which seem to conflict with his philo-

sophical views he explains allegorically.

Consul

Migne, 'Patrologia Graecae' (Vol. 66, 1859);

Volkmann, 'Synesius von Kyrene' (1869);

Crawford, W. S., 'Synesius the Hellenic' (Lon-

don 1891); Gardner, A., 'Synesius of Cyrene'

(lib. 1886).

Synge, sing. John Millington, Irish

dramatist: b. Newtown Lillie, near Rath-

farnham, 1871; d. 24 March 1909. He received

his education at Trinity College, Dublin, where

he was graduated in 1892. For about seven

years he studied music in Germany and

languages in Germany, Italy and France. He

spent several years in the Latin Quarter of

Paris where he gave his attention to the study

of decadent French literature, especially to

Baudelaire. He accomplished little in Paris but

being meanwhile interested in London, in 1897

William Butler Yeats persuaded him to aban-

don his efforts as a French literary critic and

study the social types, manners and customs of

the inhabitants of the Aran Islands, a people

ing to Relbauts and Gravier are: (a) The

sterile, (b) Emaciated gigantism, because the

internal pressure of the organ is established

late. In this case there is a prolonged infantil-

ism. (c) Emacium with castration charac-

terized by gigantism and infantile appearance.

The secondary sexual characters do not appear.

(d) The reversion infantilism of Gandy, where

simply a sort of asexual condition is noticed,

with attenuation of secondary sexual characters

and a certain degree of obesity, with late testic-

ular difficulty in the adult.

Dishyperdestiasis: Lower limbs short and

cranium very large, pilous system well de-

veloped, especially the mustache, thinness,

persestence of youth, a degree of arterial hyper-

tension, virile character, activity, moral and

physical energy.

Prostate.—Prostatic Insufficiency: Asthenia,

diminution of potency, neurasthenia, at times

suicide.

Hypertrrophy of Prostate: Arterial hyper-

tension, retardation of the heart, cerebral

hemorrhages, genital excitation.

Pluriglandular Syndromes.—Basedow's
disease with thyric hypertrophy and vagotonic

symptoms; scleroderma and tetany, ameno-

rhea; Addison's syndrome; acromegaly, etc.

Myxedematous with Thyric Hypertrophy.

Tetany, acromegaly, Addison's syndrome,

amnenorrhoea, infantilism, mammary hypertro-

phy, etc.

Acromegalic or ovarian insufficiencies with

various disturbances, psychic, nervous, vasomotor, trophic, etc., connected at one time with

the myxedematous, at another with the Base-

adowian series.

Ovarian Predominance.—Thyroid Reaction

to Ovarian Insufficiency: Tachycardia, palpita-

tions, perspirations, nervous irritability, vertigo,

shy lesion, trembling, anxiety, etc.

The differences between these nervous man-

ifestations and the picture of the attenuated

forms of exophthalmic goitre are very slight,

says Leigl-Lavaste. This pathogenic con-

ception permits of important therapeutic results;

one may ask, for example, whether the anti-

Basedowian therapy with hematothyroidin

would not be of advantage in the nervous and

psychic disturbances of the normal menopause

which repeat one feature after another of the

Basedowian series.

Dyshpersion of the Hypothyroid: Antici-
pation, prolongation and copiousness of

the menses, menorrhagia, metrorrhagia.

Thyro-ovarian Disturbances of the Same

Significance: Either ovarian insufficiency in

the myxedematous series, or the dyshyper-

ovarian in the Basedowian series; in either case the

nervous disturbances of the dysthyroid are

modified by all the factors of the ovarian

rhythm, whatever they may be.

Hyperthyroid Predominance.—Infantile

vitality, with their clinical varieties: feminism,

 comunism, cryptocardism, feminine pseudo-

hermaphroditism, mental infantilism.

Acromegalics with deficiency syndromes,

myxema, infantilism, amnenorrhoea, obesity,

et alia.

Acromegalics with syndromes of hyperactiv-

ity, more or less vicious, synergetic or substitu-

tive, simple or exophthalmic goitre, arterial

hypertension and atheroma, lacteal secretion
SYNGENETIC.—SYNODICAL PERIOD

I retained their primitive Celtic culture. They settled in Dublin where he became a literary advisor to the Abbey Theatre where he produced his dramas. These have been poems and plays which they “provoked” when produced in 1 and in the United States. His first play, “In the Shadow of the Glen” (1903), was followed by “Riders to the Sea” (1912). He was a pioneer writer in Irish literature, especially in prose. His novel, “The Tinker’s Daughter,” although written in 1902, was not published until 1909. The next significant event in his career was the publication of “The Will of the People,” a play about a peasant revolt in the West of Ireland, in 1906. In 1907, he published “The Play of the Western Riders” in Irish. This play, along with several others, established him as a prominent figure in Irish literature.

SYNGNATHIDÆ. See PIPER-FISHES.

SYNNÖVE SOLBAKKEN, sin’ê-vê’ sôl-bäk’ken, a peasant-romance by Björnstjerne Björnson, was published in 1857. Although this was not the first appearance of a work by Björnson, it was one of his most popular and influential. The story is set in Norway and concerns the life of a peasant family during the Middle Ages. The main characters are the peasant girl Synnöve and her lover, Peter. The story is filled with descriptions of the peasants’ lives and their struggles against poverty and ignorance.

SYNOD, an ecclesiastical deliberative and legislative assembly. The word is synonymous with council, but ecclesiastical assemblies are commonly called councils and minor ecclesiastical assemblies synods, though these are also styled councils. A diocesan synod is composed of a bishop and the clergy of a diocese; a provincial synod, of an archbishop (or metropolitan) and the bishops suffragan to him; a national synod of all the metropolitans and bishops of a nation. In the Presbyterian Church, synods are courts of review immediately superior to the presbyteries and consist of all the ministers and elders who are members of a number of contiguous presbyteries; the supreme council of the Presbyterian Church is the General Assembly.

SYNODICAL PERIOD, is the period between two successive conjunctions or oppositions of a planet with the sun, as observed from the earth. A synodical month is a lunation, being the period from full moon to next full moon.
SYNONYMS — SYNTHESIS, CHEMICAL

full moon or from new moon to next new moon. A synodical month is 29 days, 12 hours, 44 minutes, 2.37 seconds.

SYNONYMS, words of the same language which are the precise equivalents of each other; in popular acceptance, words sufficiently alike in general signification to be liable to be confounded, but yet so different as to require to be distinguished are synonyms. The following pairs of words are pairs of synonyms: teacher, instructor; resemblance, similarity; supposition, hypothesis; beginning, commencement. But words commonly regarded as synonymous are seldom perfectly so, as is seen in works on synonyms. There is always going on in a language a process of "desynonymization" which tends to restrict one member of a synonynous pair to one meaning, the other to another. For example, "wave" and "sillow" originally meant precisely the same thing; but "sillow" is now restricted to poetical use, while "wave" is used chiefly in practical matters. The study of synonyms is a valuable intellectual discipline in itself, apart from consideration of its high importance as a guide to the right use of words. The habit of thorough investigation into the meaning of words, and of exact discrimination in the use of them, is indispensable to precision and accuracy of thought, and it is surprising how soon the process becomes spontaneous, so that one often finds himself making nice and yet sound distinctions between particular words which he has never made the subject of critical analysis.

Consult Crabbe, George, "English Synonyms" (new ed., New York 1911); Fernald, "English Synonyms and Antonyms" (ib. 1896); Ordway, E. B., "Synonyms and Antonyms" (ib. 1913); Roget, P. M., "Thesaurus of English Words" (new ed., ib. 1914); Smith, C. J., "Synonyms Discriminated" (3d ed., 1885).

SYNOPSIS GOSPELS, those called of Matthew, Mark and Luke, which regard events generally from the same point of view and present strong resemblance to each other. Four hypotheses have been offered to account for the correspondence of the synoptics: (1) Derivation from some common written original. (2) Priority of one of the three and recurrence to that by the authors of the other two. (3) Derivation of all three from the same source independent of tradition. (4) Derivation of all three from the oral tradition, but consultation of Matthew's gospel by Mark; of Matthew and Mark by Luke. See BIBLE.

SYNOVIAL MEMBRANE, the membrane lining the various joints or articulations and which secretes a peculiar fluid — the synovial fluid — for the lubrication of the joint. See JOINT; MEMBRANE; ARTICULAR.

SYNOVITIS. See ARTICULAR; JOINTS.

SYNTAX. In grammar, proper arrangement of words under established rules and according to the best usage in order to express ideas. A word expresses a single notion, but language has more than an animal sound meaning, like the cries of animals, a wish or a feeling. A combination of such sounds, properly arranged and connected for the expression of ideas, becomes language. The art of constructing sentences is literature, not less important than the power of speech; it is indeed the intellectual part of language and a characteristic of reason. The first step in syntax is the analysis of sentences; a clear mutual relations of the several members of a sentence makes the usual rules of syntax appear self-evident truths and in most cases superfluous. See GRAMMAR; PHILOLOGY.

SYNTHESIS (Lat. synthesis, from Syn + thesis, combination, composition), the combination of individual objects or elements of thought into a whole. Thus, by synthesis separate propositions are combined into a system, or simple concepts into compound and complex ones. In this manner one recognizes that various properties, taken together, constitute the characteristics of some one object. The process, however, does not destroy the identity of the component parts, but merely correlates them into a unity. It is, therefore, the opposite, or complement, of analysis (q.v.), which is the process of distinguishing within some given object the various characteristics of that object, without, however, destroying its unity. Hence the name synthesis is applied in mathematics and philosophy to a process of reasoning working to a conclusion from propositions that have already been demonstrated, or principles that have previously been assumed or established.

SYNTHESIS, Chemical. The building up or formation of chemical compounds from their elements or groups of their elements. The opposite of analysis, one meaning of which is the breaking up or decomposition of a chemical compound into its elements. Thus the formation of water from its elements hydrogen and oxygen is synthesis, while the decomposition of water into hydrogen and oxygen is analysis. Many of the most important manufacturing processes are synthetical. The synthesis of compounds from their individual elements is of great scientific but of little technical interest. However, the recent synthetical process of unifying moist nitrogen and oxygen to form nitric acid by use of the electrical discharge bids fair to be of great interest to mankind because of the use of nitrates as fertilizers. The synthesis of compounds from groups of their elements is of very great industrial importance. Sometimes only a single and simple chemical reaction is required, as, for example, the action of water on quicklime to form slaked lime, while others, such as the manufacture of indigo from naphthalene, require many and complicated changes. There is a great difference as to the ease with which elements or groups of elements unite to form compounds. Some unite readily under ordinary atmospheric conditions of temperature and pressure, while others may require the action of heat, light, electricity, presence of water, etc. Phosphorus and iodine unite the moment they come in contact. Phosphorus and oxygen unite slowly at ordinary temperatures but with violence if the temperature is raised; sulphur and iron do not act at all in room temperature but do so when heated; hydrogen and chlorine do not act in the dark at ordinary temperatures but do so with explosive violence if exposed to the light; ammonia and hydrochloric acid or the mixture of tartrate or soda and cream of tartar used in baking powder do not react when dry but do so in the presence of water.
SYphilis

tically supreme for more than three centuries and was not definitely overthrown until 1838. At the present time we pre-

t the laboratory by synthetical processes. Aion of a "vital principle" or "vital force" ought to be necessary. Wöhler showed be not true when (1828) he prepared organic substance produced by animals, microorganism cyanate. Since that time an e number of other organic substances been prepared by synthetic processes. f the well-known ones are oil of winter-

indigo, caffeine, alizarin, etc. The pro-

ised in synthesis have been so thoroughly that the chemist has only to find out the hemical structure of a compound to be prepare it in the laboratory. Sometimes batory processes are too costly to be nical importance, but often they are of ommercial value. See INNGO; ALIZARIN.

y substances are prepared by synthesis ver existed in any plant or animal. They cly laboratory products. To this class most dyestuffs, many valuable medicines among them quinine, are contributions of es. Consult Berthelot, P. E. M., 'La e chimique' (Paris 1876); Posner, The-

ehrbuch der synthetischen Methoden g 1903); Lassar-Cohn, 'Arbeitsmethoden der Chemische Laboratorien' (2 vols., rg 1907).

PHILIS. This is a general infectious n chronic in character, which may be nicated through inculcative contact or itted by inheritance. In the acquired t first produces at the point of inocula-
specific ulcer caused in the character, fol-

by a gradual infection through the com-

ating lymphatic vessels and eruptions the skin and mucous membranes. Later, develop in the connective tissue, or in rt of the body, adventitious new growths may undergo suppurative or destructive s.

history of syphilis is shrouded in ty; certain writers have sought to trace it back to a remote antiquity. It is f syphilis was well known to the s, and that descriptions of morbid con-

applying to this disease are found in the Egyptian papyri, Assyrian and Baby-

scriptions, as well as in the ancient z and Japanese literature and the books Vedas. The evidence which connects v these ancient historic records is indefinite and inconclusive. Our actual ge of syphilis dates from the appear-

f the disease in Europe about the year and there is much evidence to show that ease was native in South America and ought to Europe by Columbus' sailors. can be no question that gonorrhea and e affections of the genital organs re-

from sexual debauch and uncleanness well known and frequently spoken of by writers. With the eruption of syphilis ppe toward the close of the 15th century, widespread extension, the identity of haw number of eyes in substantia i the appearance of this newer and more formidable

During a long period all diseases of vital organs were regarded as identical in and nature. This doctrine reigned prac-
SYPHILIS

SYPHILIS. After the second incubation the disease is said to become constitutional, although it is not definitely known at what precise time generalization of the virus takes place. Not infrequently there is, during this period, some evidence of constitutional disturbance—headache, neuralgia and febrile disturbance, more or less pronounced—which usher in what are recognized as the constitutional signs of syphilis, in the shape of eruptions upon the cutaneous surface or the mucous membranes.

The secondary stage occurs usually from 18 months to two and a half years in duration. The secondary eruptions are not continuously present, but come out in successive crops. The completion of this stage may mark the definite end of the disease, or there may succeed the tertiary stage, characterized by the appearance of gummatous formations which may affect the sub-cutaneous tissues, the periosteum, the bones and the internal organs of the body. The duration of this stage is practically indefinite. The tertiary lesions may continue to recur for 5, 10 or 15 years, or even during the lifetime of the individual. This division of syphilis into stages is somewhat artificial. It does not always pursue this regular and methodical course, with an early formation of secondary and tertiary lesions; there is not always a sharp limitation between the stages. Secondary manifestations may continue to recur for several years.

Syphilis, as we comprehend it to-day, has a much greater significance in its relation to the health of the individual than was formerly supposed. Our conception of the range of its pathological action has been gradually enlarged with increasing knowledge of the vast complexity and far-reaching character of its mutilating processes. While it was formerly known that syphilis was a constitutional disease and capable of causing changes in the internal organs, these systemic complications were regarded as few in number and of only occasional occurrence. The sporadic manifestations which took place upon the surface of the body were thought to constitute practically the entire expression of the disease. At the present day, secondary manifestations are regarded as of subsidiary importance, since they rarely compromise the integrity of any important organ. The tertiary manifestations of the disease—cerebral, spinal, vascular, ocular, pulmonary, intestinal, hepatic and renal affections—constitute the chief significance, as well as the individual danger, of the disease. The tertiary lesions of the brain and cord occupy the first rank in frequency as well as in gravity. Of all the menaces to the life and health of the individual from syphilis, lesions of the nerve centres are the most to be feared. The pathological field of syphilis has been greatly extended by the inclusion of a group of affections, badly termed parasyphilic, which, though of syphilitic origin and nature, are extremely refractory to specific treatment and practically ineradicable. As types of this group, certain diseases may be mentioned: locomotor ataxia and general paralysis. It has been stated that every hemiplegia occurring in middle age addicted to alcohol or affected with lesions of the circulatory system is, in nine cases out of 10, of syphilitic character. Practically all cases of paresis and tabes dorsalis are due to syphilis, and the spirochete has been found in the brain spinal cord in these diseases.

Syphilitic Heredity.—From a strictly sociological standpoint, the hereditary consequences of syphilis are of the greatest significance. Its prevalence and incidence give to syphilis an especial importance as a factor in the degeneration and depopulation of the race. Syphilis is recognized as the perfect type of a hereditary disease. No other disease is so susceptible to hereditary transmission, so pronounced in its influence, and so destructive to the offspring. The hereditary influence of most other diseases is manifest in the transmission to the offspring of a constitutional protoplasmic state, characterized by a feeble organization and diminished resistance to disease. In tuberculosis and leprosy, for example, the influence of heredity is limited to the creation of a predisposition to disease, from an enfeebled capacity of resistance of the organism, which renders it readily susceptible to the action of the germs of disease. In syphilis, there is a direct transmission of the specific qualities contained in the sperm or seminal cells, with the result that the normal process of nutrition are vitiated and the production conception is impeded in its development or is destroyed. No disease has such a murder influence upon the offspring as syphilis.

Syphilis may be transmitted by indirect heritance through the specifically infected sperm or ovule at the time of impregnation or from the utero-placental circulation in the course of pregnancy. Post-conceptional syphilis is applied to cases where the mother—or even both parents—may be healthy at the date of conception, the wife is infected during the course of her pregnancy and she in turn transmits the disease to the child in utero through the vascular channel of the utero-placental circulation.

Syphilis may be transmitted directly from the father, the mother remaining healthy, though in most cases the mother is infected by the fetus in utero. It may be transmitted directly by the mother, the father being healthy. The paternal hereditary influence is actively restricted; the influence of maternal heredity is much more certain and pronounced. When both parents are syphilitic, the child is almost inevitable—especially when the disease of the parents is recent and active. The percentage of deaths from mixed heredity varies from 60 per cent to 86 per cent. The quality of hereditary transmissibility is not impressed upon the syphilitic organism permanently. As the disease grows older there is a progressive enfeeblement of the transmissible power, until it finally becomes extinct. Influence of heredity is rarely manifest in the fourth year; still, there are many authenticated cases in which it may be shown over a period even longer. The attenuating influence of time upon syphilitic heredity is shown in a series of successive pregnancies. The first pregnancies terminate in abortion, which occur at a later and later period; then, still-born children, or children bearing at birth but which die soon; then, syphilitic children, surviving but showing evidences of specific taint; and, finally, healthy children, free from all signs of the paternal disease. Specific treatment also exercises a powerful corrective

* the result is a monstrosity.

* Syphilis as a Social Danger.— It is now
generally recognized that syphilis, with alcohol-
* and tuberculosis, are the three great plagues
* of our time. Owing to its wide prevalence and the dangers to the per-
* sonal health and life of the individuals affected, syphilis constitutes a serious menace to the pub-
* lic health. The amount of morbidity from this
cause in any country or community is an un-
* known and unknowable quantity, since owing to its secret and shameful character cases of
* this disease are not subject to official registrat-
* the spread of syphilis is favored not only
* the fact that its contagious activity and
* transmissive power persist during a prolonged
* period but because it is exceedingly prolific in
* its sources and modes of contagion. While it
* is commonly propagated through sexual rela-
* tions, syphilis is not necessarily so contracted.
* It may be conveyed by accidental inoculations,
* in the ordinary relations of life, in various
* industrial and professional occupations. Kiss-
* ing is a very common mode of infection and a
* very large number of cases of contagion occur
* in this way. A syphilitic infant may infect a
* healthy nurse, or a healthy infant may receive
* infection from a syphilitic nurse in the act of
* suckling. Syphilis may be transmitted through
* the intermediary of any object upon which
* the secretions of the syphilitic have been acciden-
* tally deposited. It may be conveyed in wash-
* ing vessels, spoons, knives and forks, household
* effects, pipes, toilet articles and other objects
* too numerous to mention. Certain occupations
* favor the spread of syphilis, especially that of
* glass blowing, where the infected blow-pipe is
* passed from mouth to mouth. Syphilis is not
* infrequently communicated in barber shops,
* through razor wounds or through the use of
* shaving brushes, soap or towels. Infections in
* professional life are not uncommon. Physicians
* and accoucheurs have acquired syphilis in the
* examination and treatment of syphilitic
* patients. Every syphilitic individual is the
* source of possible danger to persons with whom
* he comes in intimate contact. A case of syph-
* ilis in a family may be the origin of many in-
* cent infections. The syphilitic child may infect
* the nurse and members of the family; these in-
* turn may affect others. Veritable endemics of
* syphilis, amounting to 10, 15, 20 or more in-
* fections, have originated in this way. It is this
quality of expansiveness, this capacity of morbid irritation through family and social life, that gives syphilis its superior significance as a social danger.

It is especially, however, in its relation with marriage that the ravages of syphilis as a social plague are of the highest interest and importance. By its inhibitory influence upon the productive energy of the family, syphilis may seriously compromise or entirely defeat the social aim of marriage—the raising of children. When it does not destroy the product of conception, it may blight its normal development. The subjects of inherited syphilis that survive are stamped with inferiority and compelled to pass through life bearing the stigma of degeneration or disease. A syphilitic man should not marry so long as he is capable of carrying contagion to his wife or begetting syphilitic children. Since the contagious and transmissive power of the disease is gradually exhausted, syphilis constitutes only a temporary barrier to marriage, which may be removed by time and treatment. It may be formulated as a general maxim that a man should not marry until after a certain period (on an average four years) has elapsed since the date of his infection, during which time he should receive sufficient specific treatment. A still longer period of probation would afford an additional guarantee of safety. It is to be observed, however, that there may be contra-indications to marriage which arise from risks to the personal health of the individual by reason of his disease. The syphilitic man may be exposed to dangers, the consequences from his disease, which unfit him for the responsible position of head and support of a family. The possible existence of such disqualifying conditions must always be taken into consideration when the question of marriage is concerned.

Diagnosis.—The chancre or indurated ulcer which appears upon that portion of the body where inoculation has taken place, which may be at any point where the skin or mucous membrane has been broken or injured, has been regarded since the time of John Hunter as the distinguishing evidence that syphilis is present. The discharge or secretion from such a sore, as well as the blood of the individual who has the sore, both of which contain the germs of the disease, may be examined to determine whether the disease is communicated, while the period during which such communication is possible may continue through several years if the disease remains untreated. These germs produce a specific antigen, by their action upon the blood and tissues, and this forms the basis for the Wassermann test in the diagnosis of syphilis. This test works upon the theory of deviation of the complement by antigen substances contained in the syphilitic blood, blood or cerebrospinal fluid, and prevents or fails to prevent the lytic action of the hemolyzing fluid, according as syphilis is present or absent.

The Wassermann test is made in the following manner. Certain definite quantities of tissue fluid are taken from the liver and spleen of a syphilitic fetus, together with a definite volume of the blood serum of the individual upon whom the test is to be made. They are mixed in a test tube and fresh normal guinea-pig serum which contains the complement is added to the tube is then placed in an incubator, temperature of the body, for one hour which its contents are poured into a tube which contains a mixture of red cells of a sheep, or other suitable animal, in a physiological salt solution, serum of a rabbit which has been immunized beforehand with red blood cells of sheep. If the individual whose serum was placed in the first test tube actually has there will be no hemolysis of the red cells in the second tube after it has been in the incubator for the required period of time. In other words there will be no fixation of the reaction is said to have occurred. If, on the other hand, hemolysis does take place the result is negative and the individual presumptively not have syphilis, or has it in a quiescent condition. Various errors may occur. The Wassermann test, so that it is not absolutely reliable. This has resulted in the development of various modifications of test, one of which is known as the Quincke modification. The Wassermann test or the Quincke modification must be repeated at intervals of a month or two for a year or more; even it should be negative on each occasion to determine whether the disease has been eradicated.

Treatment.—Mercury and the potassium have until a very recent date been the basis of most of the successful treatment of syphilis. A great deal of enthusiasm was recently shown for the results of the salvarsan or "606" results which have been obtained by extending experience. While there is little question of the incontestable efficacy of this in causing the earlier lesions of syphilis to disappear, and even certain intractable of a later stage, yet relapses are the more common, it would appear, the use of mercury. The effect of a special treatment in preventing the dreaded manifestation of disease upon the nervous system and the essential to life is the crucial test of active value. It will be necessary for many years before we can estimate its curative value. The Wassermann test is essential in determining whether any chronic infectious disease of the nervous system is present or not.

SYR, or SIR DARYA, sēr-daˈr̩yə k’estan, (1) A river (the ancient Jaxartes) rising in the Taken from the river and flowing from the Two regions boundary of East Turkestan and southwest into the Aral Sea. It the districts of Ferchana, Samarkand and Bokhara and has a total length of 1,400 miles. In its upper course it receives
Syracuse. After leaving the mountain regions of rapid streams it flows for the rest of its course over the vast arid plains of the Syr area but receives few affluents. It here edly divides itself and numerous irriga- canals lead from it into the surrounding y. The river is navigable for 600 miles, a proposed line of steamers has not yet been installed. (2) A district of Turkestan an area of 194,853 square miles. The is Tashkend; pop. about 150,000. The tion of the district is 1,990,000.

RA, sērā, Greece, (1) An island in the Sea, the largest of the Cyclades, 13 south of Andros, with an area of about 10,000 square miles. The surface is rugged and the coast indented by numerous bays. The diversified landscape includes valleys with some barren patches. The products are wheat, barley, cotton, wine, and crops are inadequate to the needs of the population. The imports are largely composed of provisions such as flour, tobacco, sponges, valonia, etc. abut 20,000.

RACUSE, sīr-a-kūs, N. Y., city and city of Onondaga County, situated on New York Central and Western railroads, almost ex midway between Albany and Buffalo, 148 either way, in lat. 43° 9' W. The New York State Barge Canal reaches it through the Lake. Topography.—The city is at the foot of the aga Valley, through which and the city the aga Creek flows into a lake of the same name, the city, five miles long and one wide. The southern part is 1 by hills at the northern end of the lake on the east and west of the valley and considerable distance southward; the northern part is upon ground which the northward from the Erie Canal to the r boundary. There are several hills of e formation and of geological interest. iderable part of the city is situated upon ight down from the Onondaga Valley, th at point of at least 179 feet, as will the depth of a salt drill passed ha cedar log. Perhaps there is no sec the State of New York which possesses of geological interest than Syracuse and a County, and this is certainly true of +

Transportation.—Syracuse is an important railroad point, its roads being to its centre the spokes of a wheel to the hub. Passenger trains to the number of 100 arrive in and depart from the city daily. Abundant freight facilities are offered by competing lines and important advantages can also be had from the improved New York State waterways. Diverging from the state banking railroads: New York Central, West Shore, and Delaware, Lackawanna and Western. These roads not only thread some 20 counties in central New York, but several of them extend, with their connections, to the extremes of east, west, north and south. Of street railways, the trolley system embraces 95.72 miles of single track. This includes the mileage of track within the city of Syracuse, also to East Syracuse and Minoa, Eastwood, Liverpool, Solvay and Rockwell Springs. The New York State Railways operate to Utica and intermediate points; the Empire United Railways to Oswego and intermediate points; the Rochester and Syracuse to Rochester and points beyond, such as Buffalo and Lockport. All these lines carry freight and express. Pop. 25,000. The trolley lines operate from Syracuse to Utica, Watertown, Oswego, Auburn, Cortland and Rochester.

Commerce and Industry.—Syracuse ranks fourth among the cities of the State in the number and variety of its manufacturing plants; there are 700 industrial establishments, with an approximate investment of $63,957,000, and an annual production valued at $52,236,000, employing 25,000 persons. The manufacture of typewriting machines has taken on large proportions, the combined interests representing at least $8,000,000 in plant and equipment. The product is large and constantly increasing. Automobiles are produced in large numbers, and among other manufactured articles are soda ash, tool steel, canning, automobile parts, telegraph equipment, furniture, cement, chemicals, mining machinery, etc. The former leading manufacturer of salt is still carried on at the brine springs on the shores of Onondaga Lake, and the extensive chemical works of the Solvay Process Company employing 5,000 hands are a working plant. (See History in this article). The printing industry is also extensive, more than 60 newspapers and periodicals being published, several of them devoted to the arts and sciences. The wholesale trade supplies hundreds of small dealers in the surrounding country in a radius of many miles. The retail trade involves an area of 38 miles radius and conservatively speaking brings 5,000 shoppers to the city each week. Six banks have a combined capital of slightly more than $6,600,000 with a large surplus. Two savings banks have 85,000 depositors and $48,000,000 of assets.

Buildings.—The business section is completely built up of brick and Onondaga limestone mainly; there are a number of exhibits of present-day architecture and construction, such as the Onondaga County Savings Bank building, the University buildings, City Bank building, University Club, Young Men's Christian Association, Keeler Theatre, Trust and Deposit building, Syracuse Trust Company, the Hunter-Tuppen Company and
Dey Brothers and Company’s department stores, the high schools, courthouse, library and others. The Syracuse University, particularly the John Crouse College of Fine Arts, are all models of good architecture, and the Hall of Languages is a fair example of the excellence of Onondaga limestone, which exists in such vast quantities for building purposes.

Education.—The public schools are under the direction of eight commissioners, who appoint a superintendent at a salary of $4,000 per year. There are 38 public school buildings, having a valuation of $3,444,838. The number of pupils registered in the public schools for the year ended 1 July 1918, was 22,344, and in the high schools 3,358. The buildings are of brick, substantially constructed and supplied with the most modern sanitary appliances and heating apparatus. The course of study is according to the most advanced ideas, and a graduate of the high school is quite as well equipped as were graduates of most colleges half a century ago. Teachers’ meetings are held monthly under the direction of the superintendent, not only to preserve uniformity in the system, but also for the instruction of teachers in their general as well as special duties. The Syracuse University (q.v.), embracing the colleges of liberal arts, fine arts, law, medicine, forestry, and applied science, is situated on the highlands in the southeastern part of the city and has an ample campus of 100 acres. The property, including endowments, is valued at $3,156,711. There are 3,540 students in attendance; the professors and instructors number 344. It is under the control of a chancellor and board of trustees and affiliated religiously to the Methodist Church, though very liberal in this respect. The library comprises over 99,000 volumes and 43,000 pamphlets. An observatory, one of the largest in the country, is an interesting part of the tower of the buildings of the College of Fine Arts is a chime of bells, and on an upper floor in the Hall of Languages building the Central New York Weather Observation Bureau is located and maintained by the United States government. All of the athletic sports are maintained, and the secret societies have fine fraternity houses.

Libraries.—The Syracuse Public Library system including three branches and 34 stations centers in the Carnegie Building which was completed in 1905 at a cost of $150,000. The Carnegie library contains about 140,000 books and in 1918 had a circulation of 556,437 among 43,921 borrowers. The main library is the center of many public activities, including the Americanization work of the city. The service of the library is free. The library of the Court of Appeals in the Court House is one of the three best libraries of the State, by which it is maintained.

The general library of Syracuse University is housed in a building donated by Mr. Carnegie and is rich in certain lines of research material. The State College of Forestry connected with Syracuse University maintains a special library for forestry students. The College of Medicine has a well-equipped library for physicians and surgeons.

Religion and Charity.—Of churches and missions there are 116, of denominations as follows: Methodist, 23; Roman Catholic, 17; Presbyterian, 12; Baptist, 10; Episcopal, 8; Lutheran, 8; Jewish, 7; Congregational, 6; Evangelist, 2; Reformed, 2; Christian, 1; Unitarian, 1; Universalist, 1; Scien; Seventh Day Adventists, 1; missions. There are 13 cemeteries, of which Oak is stands first because of its rolling surface. Shading oaks, impressive entrance way, and costly memorials. Burials were made in the present enclosure of one of these cemeteries nearly a century ago. There are principal hospitals, namely, the Good Shepherd, Saint Joseph’s, Homeopathic, Menorah, Crouse Irving. Each hospital is a training school for nurses. The Syracuse Hospital Dispensary affords medical relief to the poor and ministers to those in need of medical care. The Orphan Asylum, the Saint Vincent De Paul Orphan Asylum and the House of PROVIDENCE are the three principal homes for orphans and homeless children, the first being under Protestant patronage, the others having Catholic support. The State Institution for Feeble-Minded Children is situated on an elevation on the western boundary of the city and is under the supervision of a superintendent and board of trustees. A small farm is connected with the institution which not only gives easy employment to a certain class of inmates, but produces a considerable quantity of supplies. The buildings are of good architecture and the grounds in their vicinity covered with a variety of shade trees and shrubs. The condition of the inmates, which is hopeless a few manifest some improvement after long and patient effort on the part of the teachers.

Public Utilities.—Water is brought from Skaneateles Lake, 20 miles away, at an elevation of 440 feet above the lake, and flows to the city through 18 miles of mains and 3,042 fire hydrants. The water works have a capacity of 1,144,000,000 gallons per day and is supplied by springs. The immediate supply is from a reservoir of 17 acres 220 feet above the main level of the city, which gives a hydrant pressure of 95 pounds. Almost every part of the city is supplied; the water bureau bears the cost of connections between mains and curbs. There are 260 miles of mains and 3,042 fire hydrants. The bonded debt for the waterworks is $4,100,000.

The fire department comprises five gasoline pumping engines and hose carts; two triple gasoline pumping engines and chemical hose carts; four steam-fire engines, tractor drawn; six gasoline combination chemical hose wagons; two horse-drawn combination hose wagons; four hook and ladder trucks, tractor drawn; one hook and ladder truck, horse drawn; one water tower;
strict chiefs' auto runabouts; one chief's motor-supply wagon; one horse-drawn wagon. It is under the command of a chief assistant and the respective capts of the several companies. The police force is 250 men and a special force of deputys, all under officers of grades from chief to constable. The inspections and parades of the chief constable show good drill and discipline and the city is rated high. The sanitary conditions are under the observation of a health officer being salaried. He is collected by day labor and is burned for a tax at a certain contract price. The statistics show an average annual rate of 13.1 per 1,000 of population.

Syracuse—The municipal government is united under the uniform charter of the second class of the State, the mayor and administrative council being in the control of the community. The mayor of 19 aldermen, representing the same wards, and with the mayor elective every two years. A president of the common council, comptroller, city treasurer, four aldermen and eight members of the board of directors are also elective. The common council is responsible for safety, having control of the fire and public health departments and of the water; the commissioner of public works, the city engineer, the corporation counsel and commissioner of charities are also members of the council. The mayor, corporation counsel and city engineer constitute the board of public works, and all contracts and furnishes all supplies to the various departments. The mayor, president, common council, corporation counsel, aldermen and city engineer constitute the estimate and apportionment, which up the annual expense budget and fixes the rates of city officers, subject to the action of the common council. The Municipal is presided over by two judges and its number number more than 3,000 a year, invested with considerable power and authority.

Syracuse—The territory now occupied by the city is also territory both north and south of known to white men, as early as 1620, when the French, and subsequently by the Eng-lish, came up what are now the Oswego and Seneca rivers, through Onondaga Lake, Ontario, and left present traces of Invasions throughout the central and western parts of the southeastern part of Onondaga County. Possession of the land was by the Indians (mainly the Onondagas), and there abundant evidence of the presence of battles has been shown by the presence of stone arrow points and hatchets. The Iroquois were more or less in the invasions, but the brunt of the resistance was with the Onondagas, who were in possession of the land. The Iroquois were more or less in the invasions, but the brunt of the resistance was with the Onondagas, who were in possession of the Six Nations, and it has always been with them. By treaties with friendly native white people and the State, the One-onas from time to time were induced to surrender their possessions, until finally they were allotted a reservation a few miles south of the city, where they were to occupy permanent homes and makes the best of the rocky hills constituting most of their land. The Onondagas, to the number of about 425, still exist, wedded to their habits and traditions. Many of them speak English and a few attend the Methodist or Episcopal mission and a goodly number of the children attend a school supported by the State. The religion of most of them is essentially pagan, and many of those who profess to be converted to the Christian faith find it difficult to divest themselves of pagan leanings. When emigrants began to come to the locality from New England as early as previous to the Revolutionary War, they were received kindly by the Indians, even if they recognized the fact that they were in sense trespassers, so that when the county was created in March 1794 there was a considerable settlement scattered over most of it. As early as 1789 the Salt Springs, long known to the Iroquois as a source of salt, became known to white settlers, and they, in a crude manner, began the manufacture of salt and sent quantities of it to the Eastern market. The State assumed control of the Springs in 1797 (20 June) and leased lots and privileges to whomsoever might desire them; during the remainder of that year 26,374 bushels of salt was produced and inspected by the State officials, the lessees being required to pay a royalty or tax per bushel produced. The annual product increased rapidly so that in 1810 452,050 bushels were made; (1820) 458,329 bushels; (1830) 1,413,446 bushels; (1840) 2,621,305 bushels; (1850) 4,268,919 bushels; (1870) 8,748,115 bushels. About 1890 the annual product began to diminish, mainly because of competition at Warsaw and in Michigan. It was estimated that at one time the Springs gave employment, directly and indirectly, to one-half of the population of the city; but with their decadence, more and more attention was given to the development of manufacturing industries, which have now become numerous, having vast capital and being the main support of the wage-earners of the city. Principal among these is the Solvay Process Company, whose extensive works are situated just across the west line of the city, on the State Barge Canal and New York Central Railroad. The company also has branch works at Delray, Mich., near Detroit, which have a capacity of about 500 tons of alkali per day. The amount of capital invested at Syracuse is estimated at $6,000,000 and about 5,000 men employed. The principal products are soda ash, bicarbonate of soda, caustic soda and crystals, of which the daily output is estimated at 1,000 tons. This company also makes coke, tar, ammonia, carbolic acid, picric acid and some other coal-tar products. Here again salt becomes both indispensable and profitable, for it is an essential element in the production of alkali, by the so-called ammonia process, which is employed here. The company gets its brine from wells which it sunk near Tully, some 20 miles south of the city, and brings the brine to its works through iron pipes. It was in the sinking of
SYRACUSE—SYRACUSE UNIVERSITY

these wells that the source of the brine which for so many years has been utilized in Syrac-
urse was found, in the mass of solid salt, ex-
tending, no doubt, for many miles east and
west. It was found necessary to discharge fresh
water into some wells, when it would become
saturated and then pumped from other wells to
these to the works. Experiments made at this point in the belief that the discov-
ery would verify the source were justified. The
supply was supposed to be absolutely inexhaustible,
but singularly enough the brine is not suitable for
the best quality of salt, which is still pro-
duced from local wells to the extent of nearly
2,000,000 bushels per year. The company proc-
cures its limestone from Split Rock, several
miles southwest of its works, bringing the ma-
terial in by means of large buckets suspended
on overhead wires and moved by steam power.
They run in close connection and continuously
and are capable of transporting 1,000 tons in 12
hours. A vast excavation has been made in the
great layer of rock, of much breadth and thick-
ness. Much of the building stone came from
this quarry before it was converted to its pre-
cent purpose. The "waste" product of the works
has been used to fill surrounding low lands un-
til hundreds of acres have been covered to
great depths and places of deposit are now so
limited that Onondaga Lake will henceforth be
used as the place of discharge. The material
is white and like marl and possesses no sus-
tenance for vegetation.

The State Fair is always a feature of the
social life of Syracuse, as well as entertainment
for thousands of people from abroad. The
grounds, situated on the western border of the
city, consisting of 100 acres, quite covered
with buildings for various purposes, embrac-
ing a very costly speeding track, are owned
by the State, under an act of the legislature
making the establishment permanent. Several
clubs of large membership, the Century leading
and much the oldest, are centres of sociability
and places for business conferences among
men, while there is one woman's club, the
Kanatenah, and many other social organiza-
tions.

Population.—When the county was created
in 1794 the county-seat was established at
Onondaga Hall, four miles southwest of the
present city centre; but the construction of the
Erie Canal and development of the salt works
caused a change of the county-seat to
Syracuse in 1827, when the population of the
county created in 1825 had increased to about
30,000. The population of Syracuse has in-
creased steadily and very rapidly, as follows:
1800, 1,819; (1810), 2,271; (1820), 3,275; (1830)
1840, 4,575; (1850), 8,114; (1860), 13,051; (1870),
18,813; (1880), 31,714; (1890), 51,843; (1900),
73,281; (1910), estimated 101,000.

FREDERICK F. NORTON,
Secretary, Syracuse Chamber of Commerce.

SYRACUSE, ancient SIVIGOSA, Sicily,
a city and port on the southeastern extremity of
the island, 80 miles southwest of Messina.
It is a harbor but has greatly de-
clined from its ancient prosperity
when it had a population of 500,000 inhabitants.
In 214 B.C. it was destroyed by Carthaginians.
At the northeastern portion, contains all that re-
 mains of the ancient city. Here are seen ruins
of a Greek temple, dedicated to Diana of
Apollo, a castle, remains of ancient baths and
medieval palaces, a cathedral built within the
columns of a Doric temple to Diana or Minerva.
There is also a museum containing valuable
antiquities, coins, etc. In the southern portion
of the town is the fountain of Arethusa, called
La Purrca by the inhabitants, whose water
became salty after an earthquake. Parts of
the walls of the ancient city are preserved, which
formerly enclosed the entire city on the main-
land, also of the two great aqueducts; a Romas
amphitheatre of the age of Augustus; a Greek
theatre of the 5th century B.C.; a temple to
Ceres and extensive catacombs; the massive
towers of the fortifications of the castle
Euryalus in the northwest, subterranean pas-
sages hewn through solid rock, etc., with end-
less ramifications in all directions. The Ear of
Dionysius, a deep grotto with a wonderful
echo, is 170 feet long, 60 feet high and 20 to
35 feet wide. Syracuse was founded by Greek
Corinthians in 734 B.C. Its early political his-
ory is obscure; it is known that it thrived and
itself sent out other colonies, becoming the
largest and wealthiest city of the Old World.
It had at one period a democratic government.
In 215 B.C. it was invested by the Romans and
defended by Archimedes for three years, but
finally surrendered 212 B.C., remaining in
possession of the Romans till the down-
fall of their empire. Theocritus and Archimedes
were natives of Syracuse. An increasing ex-
port trade is carried on in olive oil, lemons,
sugar, oranges, etc. Pop. 27,352. See W. H. Kurl.

SYRACUSE UNIVERSITY, located at
Syracuse, N. Y., was chartered in 1850.
The collegiate department, which was first
opened in 1871, was the continuation of Geneseo
College, founded at Lima, N. Y., in 1849. In
1872 the Geneva Medical College, founded
in 1835, was moved to Syracuse and became
the College of Medicine of the university and in
1873 the College of Fine Arts was organized.
This latter was an experiment in American
education and has proved eminently successful.
The College of Law was added in 1885, the
College of Applied Science in 1901, the
Teachers' College in 1906, the Library School
in 1886, the Summer School in 1901, the Grad-
uate School in 1911, the New York State Col-
lege of Forestry in 1911, the College of Agri-
culture in 1910, the School of Oratory in 1914.
The Hospital of the Good Shepherd became a
part of the university in 1915. The College of
Liberal Arts offers one course leading to the
degree of A.B. The course includes certain
required studies, one major subject (six hours
a week for two years), one minor subject (three
hours a week for two years) and free elec-
tives to complete the required number of hours.
Institution in Bible study is a part of the cur-
riculum but the courses are elective. The
Graduate School offers five degrees, the de-
grees of A.M., M.S. and Ph.D. The College of
Fine Arts offers a four year's
course in architecture, leading to the degree of
B.A., a four years' course in painting, leading to
gree of B.P., four-year courses in piano, organ and violin, leading to the degree of B.Mus., and in the college leading to the degree of B.C.L. These courses include in general history, philosophy, etc., as in history, theory and practice of the College of Medicine offers a four-course leading to the degree of M.D., and that of Law a three-year course leading to the degree of LL.B. Two years of college is spent in a college of liberal arts, in seven years the college and medical in eight and in seven years. The College of Ap- science offers courses in civil, electrical, chemical engineering, and degrees of C.E., E.E., M.E. and B.S. medical engineering. The students main- ner, historical and scientific associations the Greek-letter fraternities are well know and is one of the reasons for its popularity. There is a general collegiate course and there is a general in athletics. All business of the ath- lons is in the hands of the athletic gov- board, which includes representatives of the student body and the college. The men include Winchell Hall, Haven Hall, fall and eight cottages. Sims Hall is mitory for men. Many of the students their fraternity houses. The campus is 100 acres situated on a hill overlook- city and surrounding country. The farm is one mile from the. The buildings of the university in- the Hall of Languages, the Demarest Holden Observatory, the Library, the John Crouse Memorial (for the College of Fine Arts), the of Medicine, the College of Law, the Stadium and Gymnasium, the Gymnasium, the Emma Baker Steeple Physics, the Lyman Cornelius Smith of Applied Science (containing shops and wood work), the Administration g. Lyman Hall of Natural History, the School of Chemistry, New York State of Forestry building, the Photography r, the free dispensary, Margaret Olivia Teachers' College, the Joseph Slocum of Agriculture, nearly a block of hos- tels and the University block, one largest commercial buildings in the in- of New York State, erected for invest- poses. In 1902 the United States gov- t established a weather observing sta- th complete equipment in the Hall of ges. The library contains over 100,000 s, including the general library, the his- library of Leopold von Ranke, purchased and other special libraries in economics, etc. The Syracuse City Library and the Syracuse State Court of Appeals to students. The students number 200, of whom 1,500 are in the College- ral Arts, and the faculty, 325.

JAMES R. DAY, Chancellor.

IA, a country of western Asia, geo- ally and anthropologically a kind of peninsula of the Mediterranean, forming a bridge between north and south, connecting Asia Minor and Mesopotamia with Egypt, and bounded by the sea on the west and by the desert, only some 60 miles inland (at the narrowest part) on the east. The name "Syria" is rather a geographical expression than a geographical fact, for the region which bears that name on our maps is actually delimited by modern (Christian) geographers. The name was originally of much wider application than it is now, while even to-day, strictly speaking, it includes Palestine. The subjects of the Assyrian Empire, from the Black Sea to the Mediterranean, were known in ancient times as Assyrians or, in the abbreviated form, Syrians. These two names came at a later period to have different applications: Whereas "Syria" once meant all the Assyrian Empire and also Mesopotamia, it became usual with the Greeks and Romans to apply that name to the more western of these regions, but including Palestine. Later, on, Christian semi- ment created imaginary boundaries and the Holy Land was from a part of itself, a proceeding that gave birth to the prevalent erroneous impression that Syria and Palestine are two distinct countries. Geographically and geologically they cannot be separated; the mountains of Pale- tine, both on the western and eastern sides of the Jordan, are, respectively, the terminations of the Lebanons and Anti-Lebanon Mountains. The Jordan Valley is a continuation of the Bika Valley, and three out of the four sources of the river Jordan itself are in Syria. The district we describe as Palestine no longer means as once "the land of the Philistines," and always has included much which the Philistines never held; it was never entirely held by the He- brews for any length of time. Its boundaries correspond with the idealized limits of Canaan as divided among the 12 tribes, with the possessions of the Hebrew kings in the days of their greatness, and with the Palestine of New Testament history.

Syria, under Turkish rule, was divided into four vilayets and two "independent sanjaks" as follows: Aleppo, 33,430 square miles, pop. 1,500,000; Syria, 37,020 square miles, pop. 2,000,000; Beirut, 6,180 square miles, pop. 533,500; Lebanon, 1,190 square miles, pop. 200,000; Zor, 30,110 square miles, pop. 100,000; Jerusalem, 6,600 square miles, pop. 341,000. The last two are "sanjaks"; the whole of Palestine was in- cluded in that of Jerusalem and the vilayet of Lebanon. Total area, 114,530 square miles; pop. 3,675,000. Of the area, not more than 12,000 square miles comprise Palestine, to which also belong between 600,000 and 700,000 of the population. The ancient inhabitants called the country "Arab," of which name the Biblical "Syria" is a translation. The Arabs called it eesh-Shâm (the left) north of Mecca and Me- dia; and Yemen (Yamin) to the right of those cities. Damascus, believed to be the oldest city in the world, was the capital of the Aramaic kingdom. While the modern inhab- itants use the ancient, inclusive name Surtiya, the Arabs call both Syria and Damascus eesh- Shâm; the Turkish name is Syria (also Shâm); the Persians call it Soristan.

Topography.—Regarded in the ordinary sense of the name, Syria is the long and nar-
row district on the eastern shore of the Mediterranean, extending from the Taurus range on the north, the sea and air, to Egypt on the southwest, between 36° 5’ and 31° N. lat. and long. 33° 30’ and 39° E. The Euphrates forms the northeastern border; the Syrian Desert the eastern limits, and Arabia on the south and southwest. The Mesopotamian plains are separated by the desert from the Mediterranean coast region, which stretches nearly in a straight line from the Sinai Peninsula northward to Anatolia. The desert forms a chalk and limestone tableland rising gradually to an altitude of over 2000 feet above sea-level, stretching away southward into the Arabian Peninsula, but on the west sinking abruptly down to the long, deep and narrow depression of El-Ghor, which forms the eastern limit of the southern section of the coast region known as Palestine. Farther north the desert merges imperceptibly in the plains of Damascus and Aleppo and thus presents no natural well-defined limits to Syria on the east. Elsewhere the breadth is 440 miles, the length north and south is variously estimated at between 370 and 430 miles, with a mean breadth of 100 miles, narrowing in the south to 60 and expanding northward to 150 miles. Palestine is cut off by the Lowr Orontes (Nahr el-Asi) and Mount Hermon from Syria proper, measuring from this point to the southern end of the Dead Sea (Bahr Lut, i.e., Lake of Lot) about 160 miles, with an average breadth of 70 miles, the north and south sections of the plateau only differentiated from the North Arabian Desert by a picturesque mountain-wall, split in the north into two parallel chains—the Lebanon and Anti-Lebanon, the latter falling gradually northward down to the plains of Upper Mesopotamia, while the former is continued by the less elevated Jebel-Nusarieh as far as the plain of Antioch, about the 30th parallel. North of this plain the Jebel-Nusarieh is continued by the Giaour-Dagh and Akk-Kul to the Taurus above the Gulf of Alexandretta. These ranges condense the vapors from the sea and remain snow-clad till late in summer, giving the 10 to 16 miles’ breadth of the Syrian seaboard its luxuriant slopes, the snow-line is usually solid as far as its southern borders. The Lebanon range runs for about 90 miles southwest and approaches at some points to within 8 or 10 miles of the Mediterranean, presenting to seaward the appearance of bare, rocky walls surmounted here and there by a few snow-decked peaks, 10,200 (feet) and Jebel-Makmal (10,020 feet). From these is derived the name of Lebanon (white mountains), which was already current in the time of Moses. Despite its rugged appearance the Lebanon contains many fertile slopes and valleys, well cultivated and thickly populated. Eastward it is cut off from the Anti-Lebanon by the still more fertile plain of the Bekaa (Coele-syne Arabia), and westward from Mount Carmel by a low range of hills, the exterminy of the Anti-Lebanon rises in the Jebel-sh-Shih (Mount Hermon) to an altitude of nearly 10,000 feet, the culminating point of Mount Hermon and the Anti-Lebanon, separated by the isthmus of Lebanon, a lateral branch, which farther south is separated from the sea by a fertile plain. Within this region are situated the oldest and most famous places in Palestine, including the mountains of Naphtalim, and of Ephraim and Judah. In this range which prevents the Jordan from flowing toward the sea and compels it to follow a southern course until it loses itself in the Dead Sea. Excluding the southeastern flanks of Hermon, both the Lebanon and Anti-Lebanon ranges are of limestone formation; the former is a single ridge deeply marked from the effects of erosion by water, while from the latter five ridges diverge northward. The spaces between them is taken up by a plateau of from 4,000 to over 5,000 feet above sea-level. The depression of El-Ghor, referred to above, is the deepest in the earth’s crust, falling about 13,000 feet below sea-level, or more than 4,000 feet lower than the Bekaa plain. The four main streams—the Litani, Orontes and Alana—rise in the neighborhood of Baalbek, under the 34th parallel. They flow in four opposite directions, south to the Dead Sea, southwest and northwest to the Mediterranean, east to the Bahr el-Asi, and to Buebeh, some five hours’ journey beyond Damascus. The Euphrates, breaking the Taurus in a succession of cataracts and rapids, flows south and southeast, separating Mesopotamia from Syria and the rest of Asia Minor. It is joined by the Tigris at Kurna. The course of the Jordan are the lakes of Merom (El-Huleh) and Tiberias, and at its mouth is the Dead Sea. There are few perennial streams in Syria; the rain is quickly absorbed by the stony ground. Some of the old river-beds (wadis) are deeply eroded. The mountain chains divide Syria into three regions—a western, consisting of a narrow belt of lowland extending between the sea and the mountains, sometimes called the Lebanon valley; a central, occupied by the principal mountains of the chain; and an eastern, consisting for the most part of a bare, arid, sandy plateau, occasionally relieved by a few oases. Above all the towers Mount Hermon feasts the fertile plains of Syria and forming a valuable landmark for the guidance of caravans. The Little Ghora or plain of Gennesareth stretches west of Lake Tiberias. On the eastern border of Syria extends the interior of the country, a fertile steppe, which when artificially watered yields the most luxuriant produce. This region, which is called the desert on account of its lack of water, stretches at a mean level of 1000 feet to the vicinity of the Euphrates. It is inhabited by independent, nomadic Bedouins and frequently traversed by caravans. Beyond the Jordan, not far from Mount Hermon, rise the volcanic hills of Tuhil. To the south of Damascus lie the ancient wheat-bearing plains of Hauran and Pisgah, and the Syrian desert region in which numerous ancient inscriptions are to be found. Farther south extending the mountains of Gilead, partially wooded. The mountains of Moab form an extensive tableland, and separated by a low range of hills. Between the Haarrus and the Oasis of Damascus there stretches a broad expanse of volcanic hills, the Eastern
nitis (Tulul-es-Safa), toward the north-
ge of which stand the stupendous ruins
myra (Tudmur), supposed to have been
Solomon. The Alâ region between damascus and Aleppo forms an ex-
- basalitic upland tract for many miles
of the Orontes. Here are the ruins of
ancient cities. In the extreme north the
larger part of the Alâ region, Umk and Aie
ocupy all the space between the bend of
phrates and the coast range, and are
habited by Turkoman and Armenian
turists. This region marks the extreme
of both of these races toward the south-
West of the Umk plateau lies the Bahr-
(Lake of Antioch), a fine sheet of
cuet miles by six, formed by the junc-
tion of several steppe streams and draining to
ontes.

Flora and Fauna.—Vegetation is much
varied and luxuriant in the north than in
the south. The fertility of the soil of Syria is
by many ancient writers as well as in
the Bible. Even the Syrian desert consists,

A connecting link between the domestic
wild animals is formed in Syria by the
the cat. Each town and village is in-
with livestock to whom they were racially related, though of a
different faith—Islam. That religion is an eclectic compound of popular Christianity
and Judaism. Their language, Arabic, was most properly spoken in all Syria, while an Arabic Christian dynasty had existed in Damascus even before the invasion. These vigorous sons of the desert brought about a double process of assimilation. They learned eagerly from the natives, from the Persians and the Greeks. They were apt pupils who in many cases were not only able to improve upon the wisdom of their teachers, but also to absorb and mold all this foreign learning into the Arabic language, even to the extent of applying Arabic equivalents for the technical words of science or philosophy instead of using the Greek forms. That process of acclimatizing foreign ideas and culture is still prevalent among Syrian writers to-day. The Mohammedan invaders absorbed many of the old customs and religious traditions of the soil and adopted the old shrines of saints in different communities and gave them Mohammedan names. Through their language they impressed their own poetry, national heroes and saints upon the people with the result that the modern Syrian writers echo the voices and thoughts of Arabian bards and philosophers.

In the Syria of to-day the Christians, Mohammedans and Jews possess a common heritage of proverbs, legends, parables and superstitions. Indeed, it is no exaggeration to say that the modern Syrians are one people with the same fundamental outlook on life, despite their different religions and sects, characteristics, class distinctions and various dialects. In this happy blending of races the cultural endowments of the people are favorably exemplified by the Christian section of the population. They form a highly intelligent people with a remarkable capacity for adopting European ideas. The admixture of Greek and Arabic blood seems not to have impaired the good qualities of their Phoenician and Aramaean ancestors. The inhabitants of the coast districts are still Phoenicians in their enterprising spirit, commercial skill and love of travel. In Marseilles, Liverpool and Manchester, Syrian merchants are settled who promote the interests of their native land, extending their trading relations to Scandinavia and North America. Intelligent industry is responsible for the prosperous condition of the Beirut Christians. Here property is rare, and even engaged in some branch of industry or trade. Family life is simple and patriarchal. The women are thrifty housewives and devoted to their families, associating little with the outside world. The Greeks and Turksomans (q.v.) are alien races; the old Syriac or Aramaic tongue is spoken only by the Nestorians of Kurdistan; the Turkish officials and soldiers under the old regime spoke their own language.

Education and Religion.—Under Turkish rule elementary education was nominally compulsory for all children of both sexes, while the Ministry of Public Instruction provided for the inspection of schools maintained by non-Nestorian Christians. There were many native schools and other educational institutions maintained for foreign missions. In the numerous girls' schools instruction is limited mainly to the study of French and English. The Government has an excellent training school where women's work is taught and native teachers are trained. The rival houses of the "Sisters of Nazareth" and of the "Prussian Deaconesses" are highly praised for their labors, while the American mission especially in Damascus and Homs has been highly beneficial.

In religion the bulk of the inhabitants are Mohammedans; the Christians make up one-fifth of the total, and are divided into Greeks, United Greeks, Maronites (men resided especially in Gerami), Nestorians and Protestants. The number of Jews is estimated at 20,000. Protestantism is making rapid progress in the Lebanon. In the north dwell some Bedouin Ishmaelites who have a familiar word to speak the Jewish tongue. In the south dwell some Bedouin Ishmaelites who have a familiar word to speak the Jewish tongue.

Town.—In Syria many of the great cities in the world, such as Damascus, Aleppo, Emir, Beirut, and Tripoli, have flourished and retained their ancient names but recognizable forms. Tyre, Baalbek and other famous places either disappeared or shrank into obscurity. The principal seaports of Syria are found on the coast of what was once the home of the most famous navies of antiquity. Beirut is the chief port and has the largest and most flourishing trade in the Levant. Other ports are Latakia and Tripoli; the southern ports of Sidon, Tyre, Acre, Caesarea (Kaiser Ascalon, have lost their trade and during the centuries since the Crusades now little more than fishing villages of local traffic. Jaffa (Joppa) has recaptured its former prosperity owing to the industry and the Jerusalem Railway. Aleppo (iskandrun), in the extreme north, is the finest harbor on that coast, but is prey to stricken spot in that region (Seleucia), about 30 miles south of the town, also has a fine natural harbor. The feature of this district is that all the inhabitants are afflicted with one disease, called the "Aleppo Button," or the "Button of Sin." Each the result of a boil that always year before healing. Europeans are still affected by this disease often during only a few years in Sidon (q.v.), now called Saida, is of able historical interest.

Communications.—Of the three routes which have been the main thoroughfare between Europe and Asia—namely, the Euphrates Valley and the Indus—Syria possesses the most ancient direct route. From remote antiquity it has been a main channel by which the riches of have flowed to the East, and to the Indo-Syrian trade route has been the main route of the great powers, for the traverse between Europe and Asia. The first great traffic routes were the Phoenicians, and the presence of the Phoenician sea power was profoundly important. Their trade connections with the countries of Europe and Asia were maintained by means of the Phoenician trade routes. The Phoenicians maintained trade connections with the countries of Europe and Asia. They were especially important for the trade of the 8th to the 12th centuries. Then the Mongol avalanche...
Hauran and Syria. Europe lost her hold on the land route when the Mongols came to the Turkestan in 1279, the Indo-Syrian lines came again into a brief period of parative prosperity. By this time, however, the new trade routes of the East were under the influence of the Ottoman Empire and were therefore largely superseded by the old trade routes of the Mediterranean. The establishment of the British Levant Company in 1869 brought a new impulse to the revival of the old land route until, in 1875, the Indo-Syrian lines came again into a brief period of parative prosperity. But for the discovery of an unbroken waterway to India and the presence of the Suez Canal, this route would have remained the highway of the East. Even in the early part of the 19th century, despite the efforts of sea-borne trade, the prospects of a revival of the old land route were not bright. The proposed Ushratat Navigating Company and Railway were outward bound for a great need which Great Britain was about to recognize, but which Germany eventually took up and attempted to realize in her own way. It is not improbable that historians, delving in the diplomatic and commercial records of the 19th century, will find a place among the "causes" of the Great Powers of the silent struggle for the command of the eastern Mediterranean and the bridge between East and West. From Alexandria to Aleppo the road was now accessible to wheeled traffic. From the port of Jaffa, the pilgrims' route to Mecca and Mekkah superseded the railroad following the "routes" of the Syrian plain as far as Mesopotamia, and certain Arab tribes from the Yemen settled in Syria, particularly in the Hauran. For centuries before the end of the Christian era, Syria was a Roman province, and its magnificence of its architecture. The whole of Christian Syria, including Palestine, was wrested from the Eastern Roman Empire by the Persians in A.D. 611-614. Nomadic tribes of Arabs had from time immemorial ranged over the Syrian plain as far as Mesopotamia, and certain Arab tribes from the Yemen settled in Syria, particularly in the Hauran. For centuries before the rise of Islam the Arabs were everywhere a disturbing element to the Byzantine Empire. The new religion promulgated by Mohammed produced extraordinary results. As by magic, long-standing intertribal feuds among the Arabs disappeared — they became a united nation galvanized by religious enthusiasm. Shortly after the death of the Prophet the Arabs defeated the Byzantines and Syria fell into their hands (636). It was governed by caliphs till 883, and then passed under various masters till it was conquered by the Seljuk Turks, who gradually obtained possession of the whole country (1070-85). The first Crusade began in 1096; Antioch fell to the Crusaders in 1098. By 1118 the kingdom of Jerusalem had been established and the Franks had taken Caesarea, Tripoli and Beirut. The next 140 years included the romantic period of Richard I of England and the Crusades. The latter becoming master of the whole of Syria except the Frankish possessions (1183). North and central Syria were conquered by the Mongols in 1259-60; in 1291 the Mamelukes ended the Frank rule in Palestine and later united Syria with Egypt. After this period the history of Syria presents few points of interest; internal strife continued between the Mamelukes, Circassian sultans and Mongolian governors. In 1400 came the Mongol invasion of Timur and when great numbers of the inhabitants were massacred. War broke out in 1516 between the Ottoman Turks and the Mamelukes; the latter were defeated by Sultan Selim, and in the following
year the whole of Syria was incorporated in the Turkish or Ottoman Empire — a connection disintegrated by a series of aims later by the Great War. The more important events in the modern history of Syria are its conquest by Mehemet Ali of Egypt in 1833, and its subsequent restoration to Turkey in 1840 by the intervention of the great European powers; and the disturbances that broke out in the Lebanon district in 1860 between the Maronites and the Druses. A Maronite monk was found murdered, and suspicion fell upon the Druses. The latter made a general attack on the Maronite villages near Beirut and a large town under Mount Hermon. With a promise of protection the Turkish commander ordered the Maronites to lay down their arms. On this being done, they were abandoned to their enemies, who thereupon swarmed into their villages and massacred all men, women and children. So far from rendering the promised protection, Turkish troops were said to have assisted in the butchery. France and Great Britain intervened; a rebellion broke out in Lebanon, separated from Syria, and was put down. Its active services, however, were not required. As a result of that intervention the Lebanon district was created an independent sanjak, the governor of which was required to proceed to religious pilgrimage.

During the European War in June 1917 Syria was invaded by a British force under General Allenby who captured Beirut 31 Oct., Geza 7 Nov., and Jaffa 17 Nov. The victorious troops entered Jerusalem 9 Dec., and Palestine, separated from Syria, was created an independent sanjak under British administration.

HENRI F. KLEIN, Editorial Staff of The American Encyclopaedia.

SYRIAC LANGUAGE AND LITERATURE, one of the members of the Semitic family of languages. It is a variation or dialect of the Aramaic tongue, which covered the districts of Mesopotamia, northern Syria, Palestine, Transjordan, southern Arabia Petraea. The language of Syria, especially in its earlier form, differs very little from Chaldee or eastern Aramaic. The Latin equivalent of the name which is Syriacus and its Greek equivalent mean of or pertaining to Syria or its language.

Language. When Syriac first appeared within the view of history it must have been undoubtedly quite an ancient tongue, since its grammatical forms had assumed great definiteness, though it was subject to constant linguistic influence from the powerful and highly organized peoples by which it was surrounded. In later days it continued to be affected by Greek and still later by Arabic, the latter of which contributed to the language. Syriac was undoubtedly a very considerable body of pre-Christian Syriac literature; but this seems to have disappeared before the iconoclastic and misianary zeal of the Christian priests, though some of it may still be found in the literature of very ancient Syrian cities. Syriac differs very considerably from Hebrew, more especially in its vocal system which is much more con-
than that of either Hebrew or Arabian. Aramaic the prefixed definite article does at times become definite, but no longer definite in the sense that a fixed article is definite. Both Hebrew and Syriac have 22 letters and these are identified and form the dialectic difference of two tongues. In the Christian era the Syriac language, with its religious and theological influence, became the medium of literary expression.

The Syriac tongue possesses seven sounds (َا َا ِ َ ٣ ١ ٣) which are characterised by the living period of the language. These sounds are used in the West Syriac, from the alphabet, applying them in a somewhat different manner; while the East Syriac uses the series of dots by which they are more effective. The close relationship of Syriac to the Semitic is evidenced by the fact that the Semitic group of languages effect modifications in the sounds of the vowels in the Semitic languages, just as they do in Syriac, and the latter has a more primitive system than the former. The profuse system of suffixes to be found in all the Semitic languages has contributed to the Syriac. The Syriac verb is more than the Hebrew verb, but it is noticed that the lack of the original passive forms has been replaced by distinct grammatical forms. Inventions and prepositions shows this is a decided superiority over Hebrew.

One of the most important achievements of Syriac is the invention of the use of an auxiliary, thus enabling the Syriac to express its ideas with greater facility and clarity. The Syriac tongue, in which so much early Christian thought and the presentation of ideas many kinds which have already begun to be used at the door of a new world gious and philosophical imagination and

The Syriac language is of importance as the medium of literary expression of so much of the activities of the Christians and because of the numerous glosses of the Bible or parts thereof now known. The Syriac writers showed a great literary skill in the use of their ancestors and of the Semitic languages. The Syriac language took root and grew steadily in the direction of an analytical construction. Its choice of a tongue in which so much early Christian thought and the presentation of ideas many kinds which have already begun to be used at the door of a new world gious and philosophical imagination and
hymns and poems and 191metrical homilieshave been credited to him. Hedounced the hymns of his times much in the mood of the Hebrew prophets of an earlier age in a forceful manner and in a style rich in imagery and marked with imagination. A hundred or more of his poems still exist. Another writer of some of this period was Narses of Maelthea. To the same century belong Ihas, bishop of Edessa, who was deposed from office on account of his Nestorian writings; Dadhisho, commentator; Narsai, Harp of the Holy Spirit, poet and theological writer, many of whose poems survive; Jacob of Serugh, poet, and Philoxenus of Mabbogh, an excellent prose writer. Among the Syriac writers of the 16th century are John of Tellia; John bar Aphthonya, commentator, poet, hymn writer and biographer; Sergius of Rasain, scholar, translator and grammarian; John of Ephesus, noted church historian; Moses of Aggel, translator and writer; Marutha of Seleucia, commentator, sermon, hymn and epistolary writer; Bodh, legal writer and translator of Persian tales, and Hannana of Haldiaiah, commentator, controversialist and general writer of great activity. Among the historical works of interest written in Syriac are Chronicle of Edessa, Chronicle of Dionysius of Tell Mahre and the semi-religious works of Zacharias of Metylene. The whole body of translations made into Syriac was very large and embraced works from most of the great literatures of the day. This translation continued on into the period of Arabic domination; but Syriac after the middle of the 7th century began to be a dead language. After this period it became the vehicle of the Church and of scholars much as Latin was regarded in Europe. Therefore, the works written in Syriac during the period of Arabian domination are for the most part of a learned nature and the literature tends to run more in a humanistic or philosophical and scientific. Among the most noted of the classical Syriac writers are: Thabit ben Kornrah (9th century); Theoder bar Choni (10th century); Dionysius bar Salibi (12th century), who wrote the History of the Crusaders; Michael of Melitene (12th century), History of the World; Abularr of Gregory (13th century), commentator, grammarian and historian, and Abdisho (14th century), critic, historical writer and author of a careful work on Syriac literature.

SYRINGA—SZE-MA TS'IEIEN

SYRUS, si'rūs, Publius, Roman author who flourished about 43 B.C. After Laberius he reigned supreme on the stage, and his mimes were full of shrewd epigrammatic wit. About 200 apothegms are still extant under the title 'Witticisms of Publius Syrus.'

SYSTEM, the term applied to the rocks of a given period; thus we say that the Cambrian system of rocks was laid down during the Cambrian period, the Tertiary system during the Tertiary period, etc.

SYZRAN, si'-zá'n, Russia, a river-port near the right bank of the Volga, 90 miles southeast of Simbirsk. It has nine churches, a monastery, convent, grammar school, technical school and banks. The manufactures include leather goods and iron-ware. Trade depends upon grain, fish and salt, great quantities of grain being exported. It lies on the Rjasht-Batonski Railway. Pop. 46,234.

SZABADKA, sō'bôd-kô, Hungary, in the county of Bács-Bodrog, 25 miles southwest of Szegedin and 110 miles southeast of Budapest. The fashionable summer resort of Lake Palics lies within its confines. Its chief points of interest are the schools, hospitals, almshouse and music school. Agriculture is the chief occupation. It has considerable trade in fowls, fruit, cattle, horses, hides, wool, corn and tobacco. Linens and shoes are manufactured. Pop. 94,600.

SZECHUAN, sā-ch'oo'-ān, China, the largest province of the republic, in the west, with Tibet on the northwest and Yunnan on the southwest; area, 218,400 square miles. It is traversed and watered by the Yang-tse-Kiang and its affluents, is hilly throughout, mountainous in the west and rich in natural products, including coal, iron and other minerals. Opium, silk, salt, sugar, medicines, tobacco, hides, musk, rhubarb and white wax (produced by an insect) are exported to the annual value of $25,000,000; and European cottons and woolens are imported to the value of $15,000,000 annually. The capital is Cheng-tu, the chief commercial town Shung-king, which was opened to foreign trade in the end of 1899. Ichang was thrown open in 1877. Pop. of province 54,500,000. (See CHINA). Consult Baber, 'Travels and Researches in Western China' (London 1882); Bishop, 'The Yang-tse Valley and Beyond' (New York 1901); Hosie, 'Three Years in Western China' (ib. 1890).

SZE-MA KWANG, sē'-mā' kwang', Chinese statesman and author: b. 1009; d. 1086. He is remembered as the author of 'The Comprehensive Mirror of History,' in 294 books, the labors of 19 years. It covers a period from the beginning of the 5th century B.C. to A.D. 960. Sze-ma is also the author of 'Ki-ku-ku,' or 'Investigations into Antiquity,' which brings her history down to 1066 A.D. He also wrote a dictionary and numerous essays are ascribed to him. Consult Giles, H. A., 'History of Chinese Literature' (New York 1901), and Rémuat, 'Nouveaux mélanges asiatiques' (2 vols., Paris 1829).

SZE-MA TS'IEIEN, sē'-mā' ch'en', Chinese author: b. 163 A.D.; d. 89 A.D. Born in Lungmun, Honan, in 110 A.D. he succeeded his father,
Sze-ma Tan, as grand recorder and astronomer, and took up the historical work begun by him. It was finished in 91 B.C. and was named "Shih," or "Historical Records." It covers the period from 2697 to 104 B.C. He is also noted for reforming the calendar. The chronology settled by him still prevails in China. Consult Giles, H. A., "History of Chinese Literature" (New York 1901), and Hirth, F., "Ancient History of China" (ib. 1911).

SZEBEN, sz'ben, NAGY, nó'd'y, or HERMANNSTADT, hér'män-stät, Rumania, the capital of a county of the same name in Transylvania. It lies amid beautiful surroundings, among which there are several noted health resorts. The city, which is built partly on a hill, partly on a small river-plain, has handsome, well-paved streets and a large market place. Among the principal buildings are a large Gothic church dating from the 13th to the 16th century and now used by a Lutheran congregation, the city hall, the communal hospital, several large barracks and the palace of Bruckenthal containing a library and collections of art and antiques. There are five institutions for higher education in the city, besides a cadet school, trade schools and a number of minor schools. The principal industries are the manufacture of cloth and blankets, soap, spirits, glue and horn articles, and there are many machine shops, tanneries and two large breweries. The inhabitants are chiefly German Protestants. The formerly important trade with the East has declined. Nagy-Szeben was the capital of Transylvania, and from the 15th to the 17th century was very strongly fortified. It was a city of Hungary until under the Peace Treaty of 1919 with part of Transylvania it was included in Rumanian territory. Pop. about 31,000.

SZEGEDIN, szég'éd-én, Hungary, the county of Csongrad, on the 4 miles southeast of Budapest. It is a district. It has suffered the ravages of war, fire, and is now modern in industry and buildings. Its public buildings possessing and include municipal courts, barracks, theatres. The manufacture of paper, liquor, soda, tobacco, coarse wool, salt and tobacco. There is an important trade in wool, cattle, salt and tobacco. Boats are built in the yards of 1526 it was taken by the Turks, until 1686. Pop. 118,300.

SZENTES, sén'tésh, Hu., county of Csongrad on the le. Nearly 29 miles northeast of Theiss, contains many good buildings, a Protestant church with a fine clock, churches and a town house. The trade is based upon corn, cattle and wood, in which large trade as also in wine. It has a station of municipal trams. Pop. 31,590.

SZOLNOK, söl'nök, Hungary, a r., and market town in the county of Ják in the right bank of the Theiss. It is the principal town of the government, a steamboat service on the junction of four railways. Its buildings include a Turkish mosque now used as the ruins of a citadel and a Franciscan convent. It carries on an extensive trade in grain, cattle, salt and wood. Latter it was the scene of a Hungarian rebellion over the Austrians on 5 March, 1848, 28,900.
the 20th letter of the English alphabet and the 16th consonant, is a sharp mute consonant to which d answers as a sonant. Its earliest form both in Greek and Latin was but little different from which it still has; but in some early Etruscan inscriptions it is an s stroke with a small stroke at the top right or left: in early Phoenician Hebrew rock inscriptions it has the form  or  r. t is usually classed as a surd, less dental, but in English pronunciation it is classed with the cerebral, being with the tongue on the hard palate. In and other languages of Continental Europe it is a true dental, for in pronouncing en those languages the tongue comes close to the teeth. The same difference between English and those other lan- in the pronunciation of d. The digraph th, which in English, namely, the voice- nal fricative value which it has in throw, and the voiced dental fricative  that, then: these two sounds were rep- in the Anglo-Saxon alphabet by two characters, namely  for th in thank, and  for th in this, that: but in Old manuscripts there was little consist- ty the employment of these characters. Variations of the Irish pronunciation of rath the in thin, thorn, through, etc., is aspirate rather than a fricative, the tip of the tongue is pressed against the upper and the breath emitted with force; but in the English pronunciation of th is brought against the back of the teeth, with very slight contact, and the emitted between tongue and teeth; and: a similar difference between the Irish English pronunciation of th in that, then,  and in the Irish pronunciation the tongue is in full contact with the teeth. Th, or the diphthongal u (as in use), has the of th th, nature, natshur.—In the corre- of English and the languages it there is interchange of t with other examples: Eng. three, Ger. drei, Goth. Lat. tres, Gr. treis; Eng. thath, Ger. Lat. tectum, Gr. tegos; Eng. brother, ruder, Goth. brother, Lat. frater; Eng. th, than; Eng. thank, Ger. Dank. Very  t in an English word is represented by z kindred German word: Eng. two, Ger. zwei, toll; Ger. Zoll.

T

TETRANITROANILINE. Flàrschen, who, in 1910, proposed to use it as a commercial explosive as it was more powerful than any substance then in use, manufactured it from commercial dinitrobenzene by treating the latter with a solution of potassium nitrate, then nitration the product thus obtained with mixed acids at 20° C., or lower. The TNA separated in yellow crystals which when washed and dried had a specific gravity of 1.867 and, when heated at the rate of 5° C. per minute, a melting point of 216° C. and an explosion point of 200° C. Its rate of detonation is 5,500 meters per second. It is an efficient agent for re-enforcing detonators and as a booster, but its stability is questioned.

TNT or TRINITROTOLUENE. See TRINITROTOLUENE.

TNX, an explosive substance having the formula (CH₃)₃C(NO₂)₃ and whose scientific name is trinitroxylene. It is produced by nitrating the aromatic hydrocarbon known as xylene with mixed acids and fuming nitric acid. Several different compounds having the same percentage and radical composition may be formed, but the one produced in largest amount and the one most sought is the trinitrometaxyylene. This when pure crystallizes from alcohol with milk-white lamellas which when slowly heated melts at 176°-177° C. TNTX is used either alone or in admixture with ammonium nitrate, as a bursting charge for high explosive shells. It has also been used as a component of blasting explosives such as monachite.

T-RAIL. See Rails and Structural Shapes, Manufacture of.

T-SQUARE, a ruler used by draftsmen, made similar to the common L-shaped square, but of wood, and in the form of a T. It is often graduated in the edges and is convenient for ruling lines at right angles to a base. Sometimes the long arm is made adjustable, so that it may also be used for drawing angles.

TA-KU, tā'koo', China, a small fortified town situated near the head of the Gulf of Pe-chi-li, southeast of Tien-ting, and about 80 miles southeast of Peking. It is important as guarding the entrance to the Yung-ting River. It has been the scene of several engagements and was captured by the Allies in 1900, and after the war remained garrisoned by German troops.

TA-LIEN-WAN, tā'lēn wān', Manchuria, a bay on the east side of the extremity of the Liao-tung Peninsula, about 40 miles northeast of Port Arthur. The British fleet occupied it in 1860. It is within the territory leased to Russia in 1898. At its head is the northern port of Dalny (q.v.) which was opened to

[195]
foreign trade in 1901. The construction of a Russian naval station was well advanced when the Russo-Japanese War broke out in 1904 and the bay became the scene of war operations. The adjoining territory passed to Japan in 1905.

**TAAFFE,** tā'fē, Eduard Francis Joseph von (1806-1888); statesman: b. Prague, 24 Feb. 1833; d. Ellisbach, 29 Nov. 1895. He was of Irish descent and a Baron of Ballymote as well as Viscount of Austria; was educated at the University of Vienna and entered the civil service. Promotion followed rapidly and in 1867 he became Minister of the Interior. In the following year he also served as acting Minister-President. He had entered politics as a German liberal, but manifested a growing tendency toward Federalism, which he regarded as the only means of reconciling warring factions. In 1870 he joined with two of his colleagues in urging upon the emperor a policy in the direction of Federalism with autonomy, but being defeated in this endeavor, he resigned. In 1871 he became governor of Tyrol and Vorarlberg. In 1879 he was again made Minister of the Interior, formed a new Cabinet and remained at its head until 1893. Devotion to the cause of the emperor was Taaffe's strongest trait, and as this involved the consideration of the anti-Catholic nationalities of Austria, he bent every effort in that direction. He worked not through one party, but with any party which by opportune measures could be brought to support his policy, and he relied mainly upon private efforts, for in public he was an inferior speaker. In 1893 he was defeated in his purpose to extend the franchise and his retirement from public life directly followed.

**TAAAL,** tā'äl', Philippines, pueblo, province of Batangas, Luzon, on Balayan Bay at the mouth of the Pasig River, 13 miles north-west of Batangas, and about 50 miles south of Manila. It is named after an older town on Lake Taal that was destroyed in the volcanic disturbances of 1754. The people are mostly Tagalogs and are connected with Batangas and other towns by highway, has a well-sheltered anchorage and carries on an important coastwise trade. Agriculture, stock-raising and fishing are also important industries of which Taal is the centre, and sulphur deposits are found in the vicinity. The town is well built on a terraced hill, is an important military station and one of the largest municipalities in the province. It has good schools. Pop. about 36,000.

**TAAAL,** Philippines, a lake. See BOMBON.

**TAAAL,** Philippines, a volcano on Bombo Island in Lake Bombo or Taal, province of Batangas, Luzon, about 40 miles south of Manila. The island from which it rises is 14 miles in circumference; its greatest height is to the southwest, 1,067 feet above the level of the lake; from this point it descends and then rises to a height of 780 feet to the north. The crater is oval and the walls steep; at the bottom of the depression lies a lake; it supplies large quantities of water. The last eruption recorded took place in 1911; eruptions also occurred in 1709, 1715, 1716, 1731, 1747, 1754, 1808, 1873 and 1911.

**TABACO,** tā-bä'kō, pueblo, prov. Albay, Luzon, on Tabaco Bay, east 10 miles north of Albay, the provincial capital. It has the deepest and best-sheltered port in the province and carries on a large trade. It is the third port in Albay in importance of its shipping. Pop. about 3,000.

**TABARD,** in the times of the 1 tunic-like garment, worn over the arming the body before and behind and below the loins, but open at the shoulders downward; it had long slits in the sides reaching to the elbow and yokes embroidered with the arms of the sovereign.

**TABARI,** tā-bā'ri, Abu Jafar Ibn Djeurir, Mohammedan theologian: b. Amul, Taberistan, 837; d. 923. During the first half of his life he was the area of his learning and expatriate traveling from one centre to another of religion and speculation between Asia and Egypt, devoting himself to the study of the Koran and the acquisition of lore which jurisprudence, tradition, his philology had contributed to the Mohammedan scriptures. In a he settled at Balkh, and in the latter part of his investigation as a teacher and in Arabic. His principal works are the or (Exegesis), which contains a collection of the existing independent commentaries of all interpreters of the Koran, large additions, original and compiled by Al-Razi. It filled 25 large volumes and was published in 15 volumes the Zeitschrift der Deutschen Morgenländischen Gesellschaft (1881). His other somewhat less important, being a hit the world ("Annals") from creation to

**TABASCO,** tā-bä'skō, Mexico, a state at the head of the Gulf of Campeche. It is one of the states of the Confederation, its are 10,072 square miles. The surface is most entirely of a great flat, sloping to the sea, but in many parts so low subject to inundations. The streams, numerous, are short and shallow and greatly obstructed at their mouths by bars. The Tabasco, or Gisalva, River, is navigable for 90 miles and the Usumacinta to 175 miles. The climate is excessively particularly along the coast, and in the interior it is very unhealthy. A large portion of the state is still covered with primeval forest. The principal cultivated crops are cacao, dye-woods, vanilla, indigo, tobacco and the inhabitants are chiefly Indians. Th is San Juan Baptista. Pop. of the state 191,000.

**TABSHEER,** or TASAHSIR markable substance occasionally found hollow joints of certain species of bambo other large grasses. It is ordinarily for by splitting open the bamboo stem give a rattling sound when shaken. It is especially used to be found in the Bambusa and other related of Japan, China, Java and the Andes
tains. During the rapid growth of the bamboo shoots, their solid joints become hollow and are partially filled with water containing silica in solution. The development of the foliage leads to active transpiration; the water absorbed from the soil quickly disappears and tabasheer is the residue. It is at first jelly-like, but gradually solidifies into small milky-white masses. Physically and chemically these are practically identical with the hydrophane variety of the mineral opal. It is an open question whether tabasheer should be registered as belonging to the mineral or the vegetable kingdom. It is essentially a hydrous silica, the lime and potash which are often present being doubtless simply impurities. Its optical properties are most remarkable. According to Brewster, it has a lower index of refraction than any other solid or liquid, its refractive power being not only lower than water, but so much lower as to be almost intermediate between water and air. The history of its opalescent and remarkably phosphorescent. It becomes transparent when saturated with water and is remarkably porous. It probably possesses greater absorptive power than any other mineral, because the pores occupy two and one-half times as much space as the silica itself, notwithstanding the fact that they are invisible even under very high powers of the microscope. From time immemorial it has been highly esteemed for its supposed medicinal properties. A knowledge of the substance was introduced into Europe by the Arabian physicians and its name is of Arabic origin. Much so-called tabasheer in Turkey and Asia Minor is artificial. Consult Nature (Vol. XXXV, p. 488, 1897).

TABB, John Banister, American poet: b. Amelia County, Va., 22 March 1845; d. 1909. After private study, he was appointed in 1862 captain's clerk to the Confederate blockade-runner R. E. Lee, but in 1864 he was captured and held prisoner for seven months at Point Lookout, Md. He studied music in Baltimore, taught there, and at Racine College, Michigan, and after courses at Saint Charles College, Ellicott City, Md., and Saint Mary's Seminary, Baltimore, was ordained in 1884 to the priesthood of the Roman Catholic Church. Later he was professor of English at Saint Charles. He privately printed a book of 'Poems' (1884), and from that time wrote largely for the magazines, gathering his contributions at intervals into various collections. His volumes are: 'Poems'; 'Lyrics'; 'An Octave to Mary'; 'Rules of English Grammar'; 'Poems Grave and Gay' (1899) 'Two Lyrics' (1900) 'Later Poems' (1910). Ingenious in matter, compact in form, his length is the quairain distinguished by an effectively simple diction.

TABBY, a variety of rich watered silk which has undergone the operation of tabbying or being passed through a calander, the rolls of which are made of iron or copper variously figured, which, bearing unequally on the stuff, renders the surface unequal, so as to reflect the rays of light differently, making the representation of waves thereon.

TABBYTE, a variety of asphalt, semi-brittle, semi-waxy, containing a small percentage of ceresin; readily fusible, freely soluble in carbon disulphide; used in making paint, varnish, rubber substitute and pavings. Occurs with other bitumens in Wasatch County, Utah.

TABERNACLE (from Lat. tabernaculum, a tent), the tent in which the Ark of the Covenant was deposited during the wanderings of the Israelites in the wilderness, and subsequently in Palestine until the erection of a permanent building at Shiloh. When this building was erected does not appear in the Scriptures, but 1 Samuel iii, 3, clearly shows that it existed in the early days of the prophet. The building in which the Ark was is there spoken of as a temple. The sanctity which attached to the Jewish tabernacle led to the use of the word by Christians to designate places considered peculiarly sacred and in the Roman Catholic Church the name is given to the receptacle in which the consecrated elements of the Eucharist are retained. This is a small structure of marble, metal or wood, placed over the high altar and reserved exclusively for the Eucharist. Tabernacle is also in occasional use as a designation of Protestant churches. See Ark; Pyx.

TABERNACLES, Feast of, one of the solemn yearly feasts of Israel, directed by the Lord, as set forth in Leviticus, ch. xxiii. It is there commanded that the 15th day of the 7th month shall be the Feast of Tabernacles, to last for seven days. On the first day there should be a holy convocation and no service work should be done therein. Seven days ye shall offer an offering made by fire unto the Lord; on the eighth day shall be a holy convocation unto you, and ye shall offer an offering made by fire unto the Lord: it is a solemn assembly, and ye shall do no servile work therein. The Israelites were further directed to take boughs and branches of trees and willows and to dwell in booths seven days, to remind them of the time when they dwelt in booths in the exodus from Egypt. All orthodox Hebrews observe the Feast of the Tabernacles, which comes in the latter part of September. See Jews and Judaism.

TABES DORSALIS, an affection of the nervous system akin to locomotor ataxia and paralysis. It is characterized by a lack of power in harmonizing the action of certain muscles, the absence of such co-ordinating power being apparent first in the lower extremities, making the gait staggering and unsteady. There is no true paralysis, but sensiveness is diminished; the loss of power proceeds and the later stages of the malady are marked by such symptoms as disordered vision, incontinence of urine and exhaustion. The duration of the disease varies from a few months to several years. Its causes are obscure. A peculiar change in the posterior columns of the spinal cord and in the posterior or sensory roots of the spinal nerves accompanies it. Prolonged exposure to cold, damp, drunkenness, sexual excesses, masturbation, etc., have been regarded as causes. Many authorities believe that it is, in many instances, or even exclusively, a remote result of syphilis. It is alleged to be more common in men than in women and subjects between the ages of 20 and 50 are said to be most liable to it. The patient has an unsteady gait and walks like a drunken person, but soon recovers his bear-
ing in some degree. A difficulty in carrying out the intents of the will is experienced and in picking up an object one hand is employed to steady the other. When the eyes are shut the patient walks with extreme difficulty. Tabes dorsalis may be distinguished from disease of the cerebellum by absence of the characteristic pain at the back of the head, and of vomiting. The progress of the disease may be retarded, but the prospect of cure is nearly hopeless.

The treatment is limited to improvement of the general health: warm clothing, nutritious food and rest are the chief items. Salvarsan is sometimes injected directly into the spinal column with good results. Consult Osler, William, 'Practice of Medicine' (New York 1912).

TABLAS, ti'biyas, Philippines, the largest and most western island of Romblon province, 15 miles north of the island of Panay; length, north and south, 40 miles; width, 13 miles; area, 325 square miles. The island is mountainous; the highest peak, in the extreme north east, has an elevation of 2,405 feet; the coasts are mostly abrupt; on the west coast are several good anchorages for small craft; Loog has the best harbor. There are no good roads and few trails; communication between the towns, which are all on the coast, is by sea.

The chief industries are agriculture, stock-raising and fishing; but these are almost entirely for domestic purposes. The island is heavily wooded, but lack of communication with larger islands has prevented the development of the forest resources. Pop. about 26,000.

TABLE-LAND, or PLATEAU, an elevated flat tract of country of considerable area. In ordinary usage the term is applied to such flat areas elevated above 1,000 feet from sea-level. The level character of the plateau may be due to the horizontality of the strata composing it, the surface being formed by a resistant stratum, or it may be due to subaerial or marine denudation of a flexed and folded mountain belt, erosion having proceeded so far as to reduce the region to a nearly level tract or peneplain, which is then elevated bodily.

Any portion of the ancient mountain system not worn away will rise as a peak or mountain range above the peneplain surface, and constitute a monadnock. A plateau of this type—that is, an elevated peneplain—may be readily recognized by the disappearance of the slope of the strata composing it with the level surface of the peneplain, the two not infrequently making an angle of 90 degrees with each other. When a young plain of deposition with horizontal strata is elevated into a plateau, and the rivers begin to cut their channels down into it, it is in the beginning of its first geographic cycle. If it remains stationary at the altitude to which it was raised, the rivers will eventually seize their channels to such a depth that their bed from ocean to head is almost perfectly graded. Then lateral erosion will widen the valley bottoms, and reduce the portions of the plateau between the river valleys until finally these separating remnants of the plateau have dwindled to such an extent that they appear as ridges or peaks rising from a level plain, which latter is the modern plateau. If the river valleys cut into the former plateau. This is the beginning of the peneplain stage, and continued erosion will bring the surface nearest to a perfect plain not far above sea-level. If this is reached, the first cycle of geographic development is complete. The second cycle is inaugurated by a re-elevation of the land into a new plateau, when the whole process will be repeated. In like manner a folded mountain region may be worn down to a peneplain, and re-elevated to enter upon the next cycle of erosion. Most plateaus are probably elevated peneplains, either of horizontal strata or of more or less strongly folded and truncated strata. Into these the present drainage has incised itself more or less successfully. Thus the New England region is a peneplain plateau, of inclined strata, whose surface, moderately dissected by streams, slopes gently toward the coast. Southern New York, western Pennsylvania, Ohio and other districts are part of a plateau in which the strata are nearly horizontal and which has been more or less strongly dissected. This extends from the upper Tennessee where it is known as the Cumberland plateau. It is probably past its first cycle of erosion, and appears to have been a peneplain.

Among other noteworthy plateaus of North America are the High Plains of southern Utah, which range in elevations from 7,000 to 9,500 feet above the sea, their elevation being connected with that of the Wasatch Range of mountains. Between the Rocky and Sierra mountains extends a broad plateau from Mexico northward through British America. It averages from 3,000 to 5,000 feet in elevation, and is deeply dissected by the canons of the Colorado, the Columbia and other rivers. The portion included between the two rivers named is called the Great Basin. It is bounded on the east by the Wasatch Mountains, and on the west by the Sierra Nevada and Cascade ranges, and has a width of nearly 500 miles, with an elevation of 4,000 to 5,000 feet. It has no outside drainage, and hence the streams are short, and the water bodies saline. Great Salt Lake and Mono Lake in California are respectively on the eastern and western side of this plateau, and the surface between is arid and more or less desert. Similar conditions exist in the Mexican extension of this type of table-land—to which the name intermont plateau has been applied—is found in the great plateau of Tibet between the Himalayas and the Kuen-lun Mountains. Its altitude is about 13,000 feet, while the enclosing mountains rise from 25,000 to 29,000 feet in height. It is 1,200 miles long from east to west, and half as wide. The plateau of Quirao is 10,000 feet above sea-level and surrounded by lofty peaks rising 30,000 feet or more. That of Bolivia has an elevation of 12,000 feet with Lake Titicaca at 12,830 feet, and the city of Potosi at 13,330 feet elevation.

The plateau of Spain averages 2,250 feet in elevation, that of Auvergne, in France, about 1,100 feet. Bavaria is a plateau rising 1,100 feet. Persia is another from 2,000 to 4,000 feet above the sea. The Abyssinian plateau in Africa averages 7,000 feet above the sea, while much of the Sahara region is about 1,500 feet above sea-level. The table-land character of all these regions is marked. Owing to the dissection of the plateaus they appear as a rule anything but level to the traveler.
TABLE LAWN-TENNIS — TABOO

A comprehensive view from a summit is 1. Many of the larger plateaus are also

3 BLE MOUNTAIN, Cape Colony, Af-
flat-topped mountain with nearly per-
lar sides, situated just south of Cape
Its height is 3,540 feet.
3 BLE TURNING, in psychical phen-
the turning or movement of a table at a
usually at gatherings of believers in
manifestations. A number of persons
round a table, on which their
chel fingers lightly rest. They assume
posting state, usually sitting in a dim light,
etimes listening to soft music. After
the table begins to move, and on some as
to answer questions either by tilting
at appropriate letters as the alphabet
repeated. Faraday was of opinion that
y suppose was unduly impressed table by those who stood around it, and
been pointed out that pushing may take
out any distinct consciousness on the
those who push, and that expectant at
is known to produce such a state of the
as would occasion this unconscious
The principle involved is the same as
chant and the ouija board, and has been
ated exhaustively by the Psychical Re-
Society. Consult Podmore, F. W. Modern
ism' (London 1902). See SPIRITUAL-
BLEAUX VIVANTS, tābā'ā vē'vān
a 'living pictures'), are representations
es from history or fiction by means of
of grouped in the proper manner, placed
propriate postures, and remaining silent,

BLES, Lunar. See LUNAR TABLES.
3 LINUS, in Roman antiquity, an apart-
 a house in which were deposited the
and records and archives, and all docu-
memorating the exploits which had
formed by members of the family, or
ere connected with the high offices
y of them had filled. It was usually
opposite to the entrance.
3 QO, or TABU, a word of very ex-
meaning used by South Sea Islanders, to
something consecrated, sacred, forbid-
be touched, or set aside for particular
persons. It is applied both to persons,
and both to the object prohibited the
persons against whom the prohibi-
tends. Thus a consecrated piece of
is taboo, the act of consecrating it is
hoo, and the persons who are excluded
tering are also said to be tabooed. It
among certain tribes, for example, the
body of a chief living or dead, or
belonging to him; to eat in his pres-
anything he has touched; to cross his
otherwise than on the hands or
r a fish from which the eaters of
food is sometimes tabooed at a cer-
son in order to preserve it against a
of scarcity, etc. In the case of a serious
ment of the taboo the punishment is
death; in less heinous cases a sort of outlawry,
the neighbors being permitted to appropriate
or destroy the offender's goods.
The word "taboo" has been adopted into
English to designate similar customs among
ances, apart from those from which the term
was derived; and has assumed a coloquial sense
which is altogether non-religious and negative,
though the word was originally used more to
designate definite religious ceremonies that were
obligatory upon the tribe or upon the individ-
uals composing it. These taboos may be
erved at certain stated times and under cer-
t conditions, generally in connection with
important undertakings. In many Indian tribes
of America, the warrior who succeeded in kill-
ing an enemy was required, on his return to
home, to undergo certain purification cere-
monies before he could again resume his former
relations with the members of his tribe. Until
these ceremonies had been performed, not only
were these former relationships tabooed to him,
but he himself tabooed to the tribe; and
any one violating the conditions of the taboo
became himself tabooed. Always during the
period of duration of the taboo, the individual
or individuals subject to it are denied the exer-
cise of certain privileges; they may be
temporary or permanent; it may be ceremonial,
belonging to a fixed and definite period in life,
or it may be occasional. Most ancient races
had a particular taboo connected with birth,
puberty, marriage, death, and other times with
periods previous to birth and after death; with the
assumption of public office and with almost every
undertaking in life. Probably most of these
customs had their origin in the fear of the
superior power of certain deities or evil-dis-
opposed spirits and a desire to propitiate them.
But in time many of them came to be of a
more or less religious and formal nature, and
thus many religious observances were formerly
 taboo in character. Very numerous are the
things which have been subject to taboo; but
they may be classed under a few more or less
definite heads of a general nature. These in-
clude objects unclean in their nature, or through
mythical, superstitious or religious association;
ings supposed to belong to, in contact with,
or to be influenced by spirits or beings feared on account of their mysterious power;
strange or unknown objects or customs which
it is the part of good sense to propitiate before-
hand in case they should prove powerful and
ill-disposed. The dread power of priests and
rulers was especially feared for it was held lit-
tle inferior, if any, to that of ghosts, witches,
and the supernatural people in general, and
superstitious animals.
Opposed to those taboos of fear were those
inspired by a desire of personal advantage. Of
this nature were the offerings and prayers of
household gods and to certain deities
before undertaking any enterprise of a personal
nature. The priest, the ruler, the representative of
the tribe or the nation, performed the same
 ceremonies for them and with the same end in
view. In connection with these ceremonies
there were certain taboos. On opening a cask
or bag of wine, the first handful was only given
to all but the gods of growth and fertility who
made the production of the wine possible. The
firstlings of the flock were given to the protec-
tor of the herds, the ancient god of hunt-
ing; the first fish caught by the fisherman, the first game taken by the hunter, the first ripe fruit and vegetables grown by the husbandman were tabooed for a time, for the benefit of the possessor. There was not a movement or interest in life without its taboo of a similar nature. Not infrequently the two ruling motives of fear and hope of personal gain are found combined in the same taboo, for a much feared and punished sin, or one superior being might, if propitiated, become a valuable ally and helper in time of need.

Taboo associations had much to do with totems and every totem had its taboo. Among many American Indian tribes, a hunter might not kill the animal represented by his totem. Among certain others, only a part of such animal was tabooed. The moon being the goddess of fertility, her power was greatest when her full face looked toward the earth. Hence among many races, the planting of grain was tabooed except at the full of the moon. Yet potatoes and bulbous plants could be planted only when she showed the least of her face, for it was feared she might make the part above the ground grow at the expense of that beneath it. Among the forest tribes of the eastern United States and Canada, the killing of the ground squirrel was tabooed because he was credited with the discovery of medicines or their introduction to man. Among the Algonquins the white rabbit was tabooed for the hunter because the great culture god Nanabozho frequently assumed the form of a white rabbit. The white dog could not be eaten by the plains Indian because he was reserved as an offering to the great spirit. Among many primitive peoples, the names of the dead were tabooed for a certain length of time lest the pronouncing of them might call their spirits back to earth to incite them to unfriendly action. To such a length was this fear of the dead carried that some tribes buried the name with the departed and in its place bestowed another by which the dead was afterward referred to and remembered. Sometimes taboos were as wide as the tribe or the nation; and many of these ancient taboos have survived in the shape of national feeling against the use of certain objects.

The custom of making certain places sacred to certain deities arose out of the practice of setting apart such places for the worship of these deities, or through the fact that certain places were believed to be the abode of all powerful beings. This belief tabooed such places to all but the powerful beings who it was claimed had already pre-empted them. (See Nature Worship; American Mythology.) Consult Bancroft, 'Native Races' (New York); Frazer, J. G., 'The Golden Bough' (London and New York 1907-13); Gennep, 'Talou et totemisme a Madagascar' (Paris 1948); W. Albrecht, 'Anthropologie der Natur-Völker'; Smith, W. R., 'Lectures on the Religion of the Semites' (New York 1907); Summer, W. G., 'Folkways' (Boston 1907); Taylor, 'Te Ika A Maui, or New Zealand and its Inhabitants' (London 1870).

JOHN HUBERT CORNYS,
National University of Mexico.

TABOR, Horace Austin Warner, American miner and capitalist; b. Holland, Vt., Nov. 1830; d. Denver, Colo., 10 Apr. He learned the stonecutter's trade in his youth; removed to Kansas in 1855, 12 years later to Colorado, where he himself discovered California Gulch, a place he later named. In 1878 he with his partners struck the gold of silver in the mine in 10 years. He was mayor of Leadville and gave large sums to public buildings. Leadville, accordingly, hardly more than a month ago, was an opera house costing $500,000. In 1885 he was elected lieutenant-governor of Colorado and from February to March 1885 was a States senator in place of Henry M. Teller who entered the Cabinet. From that time fortunes began to decline and by 1897 tire accumulations had been swept away and returned to mining on a small scale. 1896 was made postmaster of Denver.

TABOR, Palestine, now called Jebel al-Arak, eight miles east of Nazareth, is in the shape of an almost square hill, the northeastern arm of the plain of Jezreel a height of nearly 1,000 feet, or 1,200 above sea-level. It is well-wooded; the green of the walnut, the rose bushes, the low white styrax blossoms, the pista oak trees—all these and many others—fying the path to the summit, where a gaze from the crown of the mountain, is a panorama of wolves, wild boars, lynxes, and reptiles. The isolation of this mountain was due to its being made by the clefts in the rock that characterize the scene of the Transfiguration. The data, however, shows that the mountain was occupied as a stronghold from the time of the Antiochus Magnus (218 B.C.) until the extent of Jerusalem under Vespasian. Natural remains still exist on the summit. Baedeker, 'Palestine and Syria.'

TABOR COLLEGE, located at Cedar Rapids, Iowa. It was chartered in 1854 as a Literary Institute, and an academic course was opened in 1857; the collegiate department was established and the name changed to College in 1866. It is non-sectarian in its beliefs, and owes its foundation and support to the Congregationalists, and is endorsed by the Congregational Conference of Iowa. The curriculum comprises the *classics, science, and arts. Diplomas are granted in the ba.

TABORITES, a group of the followers of the 18th-century German Protestant John Huss, who was condemned as a heretic by the Council of Constance, and had the stake, 6 July 1415, and his ashes thrown into the river Rhine. Others of the
as Hussites. These exasperated fol-
look cruel revenge on priests and monks

g to Bohemia by the Emperor Sigismund
 but civil war raged at intervals in Bo-
ntil 1485, when King Ladislas confirmed
ermal grant. See HUSS, JOHN.
BRIZ, tā-brēz', or TAUVRI, tā-vrēs',
 a city in the extreme northwest, about
s, from the Russian border, capital of
ince of Azerbaijan, on the left bank of
. 36 miles above its entrance into Lake
is situated at the inner extremity
phitheatre, about 4,000 feet above sea-
with hills on three sides, and an exten-
 on the fourth. It is surrounded with
of sun-dried brick, with bastions, and is
by seven or eight gates. A large por-
the population resides outside the walls,
plain around is covered with gardens,
ng the finest fruits in great abundance,
early grapes. The citadel is the most
uous building in the city. It was origi-
mosque, and is 600 years old. It con-
 a lofty edifice of brick, and though
amaged by earthquakes, is still a noble
re. Within the walls of the citadel there
annon-foundry and barracks. The most
building in the town is the fine ruin
musque (B. Jewish Mosque), which is about
rs old, and is partly covered with ara-
tiles. A considerable trade is carried
import of European goods and sugar,
er consisting mostly of cotton manu-
, principally British, petroleum from
and woolen goods, chiefly from Austria,
ance; and in the export of raisins and
uits, leather, carpet, silks, skins, cottons,
tea, etc., principally to Russia and Tur-
The imports and exports in normal years
over $10,000,000. Though still a com-
city, Tabriz has diminished in import-
what it was in ancient times; the
ations of old travelers, who speak of its
cafés and its hundreds of caravanser-
, being no longer applicable; its
and demand for speculation had ed to
about 165,000 in 1881, although in
imated at 200,000. The city has been
dly devastated by earthquakes, the mos
give being those of the years 858, 1041
21; on one last occasion 80,000 persons
posed to have perished. During the
World War the city was occupied first by
the Turks and later by the Russians.
TABULAR STANDARD OF VALUE,
a project for giving fixity to the value of money
by varying from time to time the amounts of
 gold to be paid according to the changes in its
purchasing power. The practical object which
those who advocate the adoption of this stand-
ard of value proposed is the attainment of a per-
factly stable currency for the payment of rents
or other deferred contracts. A tabular stand-
ard, therefore, if adopted would be simply an
fixed index number. (See INDEX NUMBER). Ac-
According to Jevons it is proposed that a con-
siderable number of commodities, say 100,
should be chosen with special regard to
the independence of their fluctuations one
from another, and then the geometrical average
of the ratios in which their gold prices have
changed would be calculated logarithmically.
The system involves the proposition that these
average prices should constitute the legal
standard for settling contracts expressed in
money—thus, if a note was signed in 1915
pledging the payment of $1,000 in gold in
1920, and it appeared that in 1920 that $1,000 would
then buy upon the average of all commodities
one-fourth less than it would have bought in
1915, the debtor should be compelled to pay
$1,333 to the creditor in 1920 in full satisfaction
of the debt; since in 1920 the sum of $1,333
will purchase only what $1,000 would purchase in
1915. It is claimed by its advocates that such
a standard would add a wholly new de-
gree of stability to social relations, securing the
fixed incomes of individuals and public institu-
tions from the depreciation which they have
often suffered. Speculation, too, based upon the
frequent oscillations of prices, which take place
in the present state of commerce, would to a
large extent be discouraged. The great obstacle
to its adoption is the difficulty of getting
economists to agree upon the precise manner of
fixing the standard and calculating the averages
of the several commodities, and even agreeing
upon the inclusion of the latter. The idea of
the tabular standard appears to be due to Sir
George Evelyn who advocated "a standard of
Weights and Measures" before the Royal So-
ciety in 1798. Joseph Lowe further elaborated
the idea in 1823 in his "Present State of Eng-
l." Scrope followed Lowe and nearly all
the economists of the 19th century were interested
in the tabular standard. W. S. Jevons brought
the matter into prominence in 1865, and further
elaborated it in his later works. Consult
Palgrave, "Dictionary of Political Economy";
Anderson, B. M. "The Value of Money" (New
York 1917); Price, "Money and its Relation to
Prices" (London 1896); Walker, "Money"
(New York 1878).
TABULARIUM, in Roman antiquity, a de-
pository of public records; specifically, a build-
ing for the preservation of such records which
stood on the slope of the Capitoline Hill facing the Forum. It was built (78 A.C.)
by the consul Quintus Lutatius Catulus. The
masonry of many of its great vaults and
columns is still intact, although another structure
has been erected on the old walls.
TACAMAHAHAC, the name of various oleo-
resins allied to elemi, exuded by different spe-

cies of trees. East Indian tacamahac, yielded by Calophyllum inophyllum of Réunion and Madagascar, is a dark-green balsamic resin of specific gravity 1.032, melting at 75° C. A yellow variety is produced by an African tree (Amyris tacamahac), and another kind comes from the Brazilian Icaca heptaphylla. The balsam poplar (Populus balsamifera) of the United States yields a similar resin.

TACANÁ, Guatemala, a volcano on the Mexican frontier, which rises to a height of 12,400 feet. It is one of several neighboring volcanic peaks of the Cordilleras, and is second in height to Tajumulco which reaches an elevation of 12,600 feet.

TACCA, the typical genus of the family Taccaaeae. It is represented by perennial herbs with tuberous or creeping rootstocks, large radical leaves, and dense umbels of flowers, brown, purple, or greenish in hue. These terminate a naked scape and have an involucre of bracts, the inner being filiform and pendulous, the outer herbaceous or colored. The fruit is a berry, usually three-angled or six-ribbed. Tacca spathacea, or clump, is found in Polynesia and southeastern Asia. It is a low plant, with dissected horizontal leaves and an umbel of greenish flowers.

TACHÉ, Alexandre Antonin, Canadian Roman Catholic archbishop: b. Rivière-du-Loup, Quebec, 23 July 1823; d. Winnipeg, Manitoba, 22 June 1894. After graduating from the College of Saint Hyacinth and studying theology at Montreal, he became a member of the Order of the Oblate Fathers. He then started out as a missionary for the Northwest and there began the charitable work among the Indians of the Red River country which made him famous. He was consecrated (1850) bishop of Arath, and (1863) bishop of Saint Boniface. When the bishopric of Saint Boniface became a metropolitan see in 1871 Taché was appointed its first archbishop. In 1870 while bishop of Saint Boniface at the urgent request of the Canadian government, he performed the service of pacifying the Metis of Manitoba, who had rebelled. Among his publications are: 'Vingt ans de missions dans le nord-ouest de l'Amerique' (1866); 'Esquisse sur le nord-ouest de l'Amerique' (1896), etc.

TACHÉ, Sir Etienne Paschal, Canadian politician: b. Saint Thomas, Quebec, 5 Sept. 1795; d. there, 29 July 1865. He practised medicine until 1841, when he became a member of Parliament; from 1848-49 was commissioner of public works; and from 1856-57 was speaker of the legislative council. He published 'Le developpement de la force physique chez l'homme' (1829); 'Reflexions sur l'organisatios des volontaires' (1863).

TACHEOMETRY, tâk-e-im'-etr, quick measuring, applied in surveying to a method which does away with the practice of measuring distances by a chain or tape-line and ascertaining their position by an instrument, the relative position, both horizontal and vertical, of points on the earth's surface being determined by one observation. A theodolite, or a specially constructed tachometer, of which a telescope is an important part, is employed, and along with it a staff similar to a leveling-staff, 12 feet or so in length, and marked. See Surveying.

TACHINA-FLIES, flies of the Tachinidae, a large and important group comprising house flies and noted for their feeding habits. They may at first seem rather large and gray, more or less the wings clear, the bodies bristle; and disposition to fly in the sunshine with a noise. All are parasitic and are especialy of laying their eggs upon the backs of other insects. For many insects the life of these flies consult Howard, 'The Book' (New York 1901), and the species there cited.

TACHYGRAPHY. See St.

TACITUS, tâs'-tûs, Roman emperor: b. about A.D. 56, at Cappadocia, April 27. He was descended from Tacitus, the historian, whose works he edited in all the public libraries and caused to be transcribed 10 times a year at his charge. On the death of Aurelian he was to be emperor by the Senate, although his will (275) had named the emperor the supreme council by his wish for moderation. During his short reign he ''scribed many needed reforms and end to restore the power of the Senate. Age of 75 he undertook a campaign against Alani, assuming after his victory "Gothicus Maximus." He was assassinated in 276. His own unbridled soldiers; his bro- anus Tacitus, who succeeded him, shared his fate.

TACITUS, Publius Cornelius, in ment of many competent critics, Roman historian. Neither the time place of his birth is known, but eidents in his own works and in the letters of younger Pliny (the two chief sources of information about him) make it probable ber was born about 55 A.D. His educa and political career all point to equestrian rank, and his father was probably that Cornelius Tacitus who, ing to the elder Pliny ("Natural History" 76), was procurator of Gallia Belgica. mired in 78 the daughter of Gnaeus Fulciola, the illustrious governor of Brazil, enjoyed the official favor of Tiberius Titus, and, at least at first, of Domitian whom, in the year 88, he presided as and as a member of the ancient college of Quindicemviri at the celebration of the games. After his praetorship, he was years absent from the capital, and prevented from being present at the d of Agricola, which took place in Rome. During these years he was probably a pratorian legate in a province, and gained at this time some personal known. In 97 (possibly 94) he was consul to succeed Verginius Rufus, o pronounced an eloquent funeral ora was an intimate friend of the younger years his patron, and was deceased, in 100, in the successful prosecution of Marius Priscus, accused of extortion in the province of Africa. According to an nion discovered in 1890 at Mylasa, i Tacitus reached, perhaps in the year the highest post open to a senator, t
ship of Asia. The date of his death is
unknown, but, inasmuch as the extension of
empire to the Persian Gulf, which was ac-
quired by Trajan in 115–16, is mentioned
in Vol. II, 61, and several years were
nearly required for the completion of that
empire, he may have lived into the reign of
Nerva, which began 117 A.D.
The earliest work is the 'Dialogus de Ora-
sis,' written probably under Titus, 79–81.
The scene of the conversation is laid in
the house of a poet Maternus, in the year 74–75,
and a charming discussion of the relative merits
of poetry and oratory leads up to the main
theme, the decline of eloquence in modern times.
The treatise abounds in true and striking re-
fections, and exhibits the same power of subtle
analysis that marks the later works. But the
style is distinctly Ciceronian, and in its rounded
smoothness, so different from the abrupt in-
cisiveness of the 'Histories' and 'Annals,'
shows the influence of Quintilian, who was then
preaching a return from the style of Seneca to
that of Cicero. For this reason the great Justus
Lipsius, in 1574, attributed the 'Dialogus' to
Quintilian, and since then it has been ascribed
to Seneca, Pliny and others. But the weight of
evidence is decidedly in favor of the Tac-
tian authorship.
During the 15 years of the reign of Domi-
tian, years whose horror finds sombre expres-
sion in the opening chapter of the 'Agricola,'
Tacitus published nothing. But early in 96
there appeared, in rapid succession, the 'Agricola'
and the so-called 'Germania.' The for-
mer, the story of the life of his father-in-law,
whom he evidently loved and revered, is a
masterpiece of biographical writing. The style
is no longer Ciceronian but Sallustian, rapid,
terser and piquant, rising at the close to sus-
tained sublimity. The second monograph is
commonly known as the 'Germania,' but its
exact title is differently given in the important
manuscripts and cannot be determined with cer-
tainty. It falls into two parts. The 27
sections deal with the physical characteristics
of Germany and the institutions, beliefs and
customs of its inhabitants as a whole; the as-
suming 19 describe the individual peculiarities
of the separate tribes. The treatment is rhetor-
cal and ethical rather than simply scientific, so
that the purpose of the essay has often been
questioned and the credibility of its statements
attacked. But it is regarded as on the whole
a trustworthy account of German lands and
peoples, though the geography is weak and the
description of the tribes in the interior may
have been based upon insufficient evidence.
The Germans were then the object of much
interest (Trajan was in Cologne at the time of
his accession) and Tacitus, writing to satisfy
this curiosity, pointed out at the same time to
his countrymen, the contrast between their own
corrupt civilization and the vigorous sim-
plicity of these Northern tribes, and gave
a warning of possible danger.
In the introduction to the 'Agricola,' Tac-
tius announced his intention of composing
'memoriam servorum testimoniun honorum.' The first part of this
plan was realized in the years 104–10 by
the publication of the 'Histories,' consisting origi-
nally of 14 books, or possibly only of 12, cov-
ering the period from the death of Nero in 68
to that of Domitian in 96. But, instead of adding
the reigns of Nerva and Trajan, he then
wrote the 'Annals,' in 16, or possibly 18 books,
from the death of Augustus in 14 ('Ab excessu
Divi Augusti' is the actual title of the work)
and the point at which the 'Histories' begin. Of
this remarkable achievement, the continuous
history of the empire for 82 years, there is ex-
tant about one-half. Of the 'Annals,' we have
books I–IV with the beginning of V and the
greater part of VI, and, with a gap at the be-
ginning and also at the end, books XI–XVI,
that is, we have lost almost entirely the years
29–31 of the reign of Tiberius, the whole of the
reign of Caligula, the first six years of Claudius,
and the last two of Nero. The extant portion
of the 'Histories' ends in the middle of book
V and describes the eventful year 69 and part
of 70. The treatment is obviously much more
minute in the 'Histories' than in the 'Annals,'
and this is due to the fact that Tacitus is here
dealing with occurrences which cannot well
within his own lifetime. The loss of the reign
of Domitian is especially to be regretted.
Interesting as are the minor works, it is in
the 'Histories' and the 'Annals,' that the real
sensibleness and literary art of Tacitus are revealed.
His method is essentially scientific, though
he does not use archives and original sources
as much as would a modern historian. But he
strives conscientiously to ascertain the facts and
to determine the sequence of cause and effect.
A thorough aristocrat and lover of the old re-
public, he yet bows to the inevitability of the
empire and appreciates the enlightened rule of
a Trajan. But the reign of Domitian perma-
nently embittered his soul. He was gifted by
nature with a marvelous power to trace the
hidden springs of thought and action and ex-
perience of life bred distrust and made him an
expert in the analysis of human weakness and
guilt. His portrayal of Tiberius, for instance,
though certainly prejudiced and unjust, is
extraordinarily subtle and brilliant. The style,
which we may see in process of formation in
the 'Agricola' and 'Germania,' is characterized
by pregnant brevity, leading sometimes to ob-
security, by deliberate avoidance of balance in
the structure of the sentences and by poetical
phraseology. The influence of Virgil is marked.
See GERMANIA.

Bibliography.—The standard text is that of
Halm (Leipzig 1907). The 'Dialogus' has
been admirably edited by Peterson (Oxford
1893) and by Gudeman (Boston 1894); the
'Agricola' (Oxford, 1896), and also the 'Germania'
by Furneaux (1894); the 'Histories'
by Spooner (London 1891); the 'Annals'
There is a fine special lexicon by Gerber and Greef
(Leipzig 1903). There is an excellent translation
of all the works by Church and Brodribb
(London 1905); of the Annals' by J.
Emmsay (London 1904); of the 'Histories'
by Fyfe (Oxford 1915); of the 'Dialogus,' 'Agricola,'
and 'Germania' by Fyfe (Oxford 1908)
and by Peterson and Hutton (Loeb Classical
Series, New York 1914). Consult also Bois-
sier, 'Tacitus and Other Roman Studies' (New
York 1906).

Literature, Columbia University.
TACKLE, among seamen an arrangement of two or more blocks, with suitable ropes, for raising or lowering weights. The combination is usually designed to increase the capacity of the vessel's power. One block is fixed while the others are movable. Tackles are termed luff and watch, single and double Spanish burtons, Bell's purchase, luff upon luff, etc., according to the arrangement of the bearings, pulleys, etc. See BLOCK; PULLEY.

TACKS. See NAILS.

TACLOBAN, tâ-kô'ban, Philippines, pueblo, capital of Leyte Island; on the east coast at the southern entrance to the San Juanico Strait, on the northwest extremity of San Pedro Bay. It is the northern terminus of the east coast highway, has an excellent port, with large wharves. Pop. about 12,000.

TACNA, tâ-kâ'na, Chile, (1) a province occupying the northernmost extremity of the country, a large area, 8,686 square miles. The main ridge of the Andes runs just within the eastern boundary and a lower range runs along the coast. Pop. about 30,000. (2) its capital, a city of about 14,000 population, of local importance. The Chileans defeated the Peruvians in a battle here in 1880.

TACOMA, tâ-kô-ma, Wash., third city in Washington, seaport, county-seat of Pierce County, on Commencement Bay, 38 miles south of Seattle and 25 miles north of Olympia. Its phenomenal growth has given the city the name "The City of Destiny." It is also called the "City of Beautiful Homes" and the "City with a Snow-Capped Mountain in its Door-yard." It is situated at the head of navigation on Puget Sound and is the western terminus of the Northern Pacific and the Chicago, Milwaukee and St. Paul railroads, both of which maintain large ocean docks and car repair shops. Tacoma is also the American terminus for the Osaka Shosen Kaisha, a Japanese steamship line with headquarters at Osaka. Tacoma's harbor is one of the greatest deep sea harbors in the world and because of its similarity to the Italian city, Tacoma is often referred to as the "Naples of America." 

Topography.—The Puyallup River empties into Commencement Bay within the city limits and is one of five waterways that help make up this modern port. The city is built on rising ground which reaches an altitude of 418 feet above the river. The best residence portion of the city is on a plateau, elevated about 200 feet above the blue waters of the Beautiful harbor, and from any portion of this section may be seen stretches of gleaming water losing themselves among the wooded islands; beaches, white, gray and brown, and towering headlands. The Olympic Mountains stretch along to the west, rugged, snow-capped peaks, and from near the city rises Mount Rainier, here known as Mount Tacoma. The Mountain that was God, as one author calls it, an attempt to peak, is 14,520 feet high. It is but "four hours from Tacoma to the Glaciers," from tidewater to mountain elevation. The streets of Tacoma are level and paved, and so generously and wisely is the city laid out that it has not a street less than 60 feet wide, while it has several noble avenues 100 feet wide and a few 120 feet. Neat homes—of banker, merchant, manufacturer, wage-earner—is surrounded by beautiful and pretty gardens. The climate is without its equability and mildness, the temperature being 30.6°; the highest, 98°; and the mean minimum, 39°; is 43 inches, with little or no snow.

Trade and Commerce.—Because of its strategic position, Tacoma has always had a huge water-borne commerce. In 1918, 1,666 arrivals from foreign ports were recorded, with cargoes of 2,103,656 net tons, clearances for foreign ports numbers with a tonnage of 2,103,595. The total imports and exports was $318,613,508, exports alone totaled 2,160,474 barrels, at $22,747,555. The daily capacity of the mills is 9,000 barrels. Tacoma's warehouses have a storage capacity of 75,000 bushels. From the time in 1869 schooner-load of lumber from the old mill was shipped to San Francisco, it has been the leading lumber market city of the Pacific Coast. There are 100 mills in the district in addition to the mills of Chicleaus & Co. In 1918 the exports totaled 93,500,000 feet. Tidal steamship lines operating to and from Japan and the Pacific Steamship Company have millions in construction and improving present port. The Hub for the southwestern coast and Washington, Tacoma possesses a huge sale and jobbing trade. Her jobbing in 1918 totaled $160,000,000; retail trade $500,000,000.

Manufactures.—With 1,850 business enterprises, including over 300 manufactory plants, Tacoma has approximately 50,000 wage-earners, with a monthly pay-roll amounting to $6,763,000. The total investment in 1918 was $152,000,000, the amount $27,900,000 represents the wages paid to 8,000 men, and is one of the largest laid out steel shipyards in the country. The Tacoma Smelter employing 1,000, an output of 150,000,000 pounds of copper at $45,000,000 in 1918. This were were average prices of Federal and state products, marble, iron, and other products, including machinery, boiler and marine engines.

Most of Tacoma's industries are on 1,500 acres of tidelands extending further the southern boundary of the harbor.

Pond Golf Club, Tacoma Yacht

Club, Tacoma Tennis Club, Soldiers and

Sailors Club.

Transportation.— Six railroads have ter-

or connections in the city. The Northern

Pacific and Chicago, Milwaukee and Saint

railways have their western terminals in

Tacoma, including car repair shops, and

ocks. The Great Northern and the Oregon

and Washington (Union Pacific) railroads

operate in the city, and the Great Northern has

connections with the Canadian Pacific and

Chicago Great Western railroads. Electric

interurban trains operate between Tacoma and

Seattle on a half-hour schedule; also between

Tacoma and Puyallup. There is a total of 143

miles of track operated by the local traction

company. Automobile stages on regular

schedules operate on a dozen paved highways

every city and town in Pierce County and

adjacent counties, including the cities of

Seattle, Olympia, Aberdeen and Hoquiam,

and Chehalis and Centralia. Local steamers

serve all points on Puget Sound, popularly

Victoria and Vancouver, British Columbia, and

to Pacific Coast and Alaskan ports.

Camp Lewis and Rainier National Park.—

The largest permanent army mobilization and

training cantonment in the United States is

Camp Lewis, just south of Tacoma's city

limits. The cantonment contains 76,000 acres

and is 18 miles long and 12 miles wide.

Citizens of Tacoma and Pierce County (the city

pays 80 per cent of the taxes) voted $2,000,000

in bonds to purchase the ground for the

government for military purposes. In

sequence, a full division of troops will be

maintained at the camp permanently. Paved

highways with auto transportation lead from

the city to the camp. There is also steam and

electric railway transportation.

From Tacoma automobiles convey a tourist

in four hours over one of the finest paved

highways in America to the Glaciers of

Rainier National Park and to matchless Mount

Rainier (or Tacoma, its local name), 14,520

feet high. The park is the most popular of

those supervised by the United States govern-

ment. Attendance in 1918 was 50,000, exceed-

ing that of any other national park. There is

transportation to the park over the Tacoma

Eastern to Ashford from Tacoma, giving rail

transportation to within a few miles of the

park entrance.

Education.— Tacoma is the seat of the

College of Puget Sound (Methodist), Pacific

Lutheran Academy (Lutheran), Annie Wright

Seminary (Episcopal), Academy of the Visita-

tion and Aquinas Academy (Roman Catholic).

There are eight parochial schools, six com-

mercial or business schools, and in the public

school system two magnificent high schools

and 32 grammar schools. The total enrolment

of the public schools is 18,904, including 2,000

attending night schools. There are 645 teachers

employed. The Stadium High School has a

Greek amphitheatre called Stadium which has

a normal capacity of 32,500 persons, which can

be increased to between 40,000 and 50,000.

The Carnegie Library, with two branch libraries

and branches in the high schools and grammar

schools, has 85,598 volumes with a net

circulation in 1918 of 338,237. The total value of

library property is $200,000, and the number of
registered borrowers 18,111. Overlooking the Stadium and opposite the high school are the Ferry Museum, with a large collection of Indian curios. On the use of the old home of the Washington State Historical Society.

Churches and Charities.—Nearly every religious sect or denomination has a house of worship in Tacoma, the city being particularly well equipped with beautiful churches, the total number reaching 135, the principal denominations being Methodist Episcopal, Presbyterian, Lutheran, Episcopal, Congregational, Roman Catholic, Baptist, Christian Science, Christian, Jewish, Evangelical, Friends, Adventists, United Presbyterian and Universalist; also Salvation Army and Volunteers of America.

Charitable institutions include the Northern Pacific Hospital, County Hospital, Tacoma General Hospital, Saint Joseph's Hospital, City Contagious Hospital, Western Washington Hospital for the Insane at Fort Stillicom, a suburb; the Children's Home, City Rescue Home, Parkland Children's Home.

History.—Tacoma city was originally within the boundaries of the first ward, popularly known as Old Town, now called Old Tacoma. The city was laid out in 1868 by Gen. M. M. McCarver. In July 1873 the Northern Pacific Railroad established its Pacific Coast terminus on Commencement Bay, giving it the name New Tacoma. The city was also called Commencement City. In 1880 the new town became the seat of Pierce County, and in 1883 Old Tacoma and New Tacoma were consolidated and incorporated as a city. Since that time additional territory has been annexed on four different occasions, giving the city a total of five taxing districts. The present area of the city is 25,168 acres of land and 2,752 acres of water, or 39,81 square miles. The distance from northern to southern boundary is seven miles. The 35 wharves and docks have a lineal front of one and a half miles.

Population.—Government census (1880) 720; (1885) 1,100; (1890) 36,006; (1900) 37,714; (1910) 83,743; (1 Jan. 1919, local estimate) 142,447.

EDWARD P. KEMMER, Managing Secretary of the Tacoma Commercial Club and Chamber of Commerce.

TACONIC (ta-kön'ik) MOUNTAINS, a range extending nearly north and south, uniting the Green Mountains of western Massachusetts with the Highlands of the Hudson. The highest peaks are Equinox in Vermont, 3,847 feet, and Greylock in Massachusetts, 3,305 feet. The Taconic system, in geology, was named from the characteristic strata of this range, a metamorphic rock, believed to be older than the Silurian system.

TACONIC SYSTEM, a term applied by Prof. Ebenezer Emmons, in 1842, to certain azoic and paleozoic rocks occurring in the eastern part of New York and western parts of Vermont and Massachusetts. These he believed to be the equivalents of the Cambrian rocks of England. Subsequent investigations have shown that Emmons misread the geological structure of the regions studied by him, and his arrangement of the strata has, therefore, been set aside. The subject has given rise to much discussion among American geologists.

The Taconic System is nowhere reached in the Taconic Mountains, but it is described and illustrated in 'The Geology of the Taconic System of Emmons,' by Professor LeRoy Pelley, and in 'Some Observations on the Taconic System of Emmons,' by Professor LeRoy Pelley, and in 'Some Observations on the Taconic System of Emmons,' by Professor LeRoy Pelley, and in 'Some Observations on the Taconic System of Emmons,' by Professor LeRoy Pelley, and in 'Some Observations on the Taconic System of Emmons,' by Professor LeRoy Pelley, and in 'Some Observations on the Taconic System of Emmons,' by Professor LeRoy Pelley.}

**TACTICS.** Tactics has regard to the actions of an army in the actual presence of an enemy, and may be defined as the strategy on the battlefield or the science of maneuver and combining those military units which discipline and the regimental system brought to the perfection of machines. It is admirably described by Napoleon as the 'stronger'—that is, of bringing overwhelming force to bear on any given whatever may be the relative strength of entire armies opposed. The earliest recorded use of the word in antiquity was in the phrase 'the stronger overcomes the lighter.' The growth of democracy arose the organization of the phalanx, the adherents of which were irresistible; and its firmness equally charged in front. It, however, changed with great difficulty; was much deranged in the war against the French; and was finally abandoned in a suit, or if attacked in flank. Far lighter and more mobile was the Roman legion. Among Roman tactics was also the admirable intrenchment which they scarcely ever omitted as a natural source of strength for their position.

Events reproduce themselves in cycles, with decay of Roman civilization came the mail-clad heroes and cavaliers—men this time on horses—who monopolize the ords of battle, while the undisciplined foe had an undue share of the dangers. Later, in the feudal period, this disparity between foot and foot was diminished by the employment of bodies of archers, whose shafts riddled distant death. The adoption of gunpowder for small arms altogether neutralized the superiority of the armored knight. This, c Forgna brought infantry into the front line in mass, and threw cavalry into the status of an auxiliary. The French Revolutionary Wars brought to the development of artillery as a weapon and Napoleon employed this to its fullest extent, a practice followed by the best modern generals, who never a man where a cannon ball can do the greatest damage. Frederick the Great was considered an excellent tactician for fighting with infantry, and he employed the French system of tactics to a great extent. Before the battle of Waterloo, the British leaders had acquired sufficient confidence in their troops to use them in a double line.

In the battles of Gravelotte and Sedan the turning movements were complete losses of the tenth German division at Vaux prove what a serious matter it is to make direct attack against the breach-loading battery, amounts to about 4,000 men. It is necessary to make vigorous attacks on points of the French position, so as to
TACTICS

continued this march until the fire caused a break in their lines and a retreat, or until they reached the work after enormous losses and held it as the result of a hand-to-hand fight. The skirmish line was so small in comparison with the main force that it really amounted to nothing and the attack was in fact made in solid line. The attack and the forward movement were not distinguished. This defensive formation was the principal cause of the heavy losses.

In offensive tactics we may consider three general modes of attack, one of which the commander of a combined force must select as the most suitable for his purpose: (1) Frontal attack, which would mean a direct advance upon the whole of the enemy's line or position. As a general rule, this form of attack is unadvisable, as even in case of success the result is not decisive; the enemy's line of retreat being unassailed, he simply falls back to a position more to the rear. There may, however, be situations when the nature of the ground prevents any other mode of operation, or where the frontal attack may be made use of to feel the enemy and to determine his exact dispositions, in preparation for a concentrated attack upon one of his weak points, as soon as they are discovered. (2) Combined attack upon front and flank. In this case the enemy is attacked in front at the very time that a portion of the force is directed at one of the flanks. An attack upon the flanks by itself unaccompanied by a frontal attack is not advisable, except in the case of small detachments acting against one flank; unless the attack can be effected by surprise, in which case the enemy is unable to meet it in time by a change of front. Were a strong force in position attacked solely on the flank it would quickly form up its reserves to a new front, the troops of the original front coming up in support. For a flank attack, therefore, to succeed, it must, as a general rule, be accompanied by a frontal attack, sufficient to hold the enemy to his original position. An attack upon both flanks combined with a frontal attack can only be tried under circumstances of great superiority of numbers, without which it would become a most dangerous operation, enabling the enemy to give the counter-stroke of a weak point of a straggling line and beat the assailants in detail by cutting their force into two. In engagements where the numbers are small the flank attack may be made alone. (3) Concentrated attack upon a weak point, to break through the enemy's line or force his position. This mode of attack, if the most difficult of execution, is undoubtedly in case of success the most decisive, the enemy being broken into fractions which can subsequently be beaten in detail. The enemy's line of retreat may also thus be arrived at, and his communications cut before he can recover himself. The attack must always be made with force sufficient to resist a counter enveloping attack on the part of the enemy; which might otherwise be disastrous in its results. The increased range of modern guns and rifles has made this attack more hazardous than ever, for a concentrated fire-action can now be brought to bear on the assailant, not only from all parts of the defense in his immediate front, but in most cases from either flank as well.
Unless, therefore, the ground covers the movement in a great degree it should not be attempted.

In addition to the above primary modes of attack, a movement may also be considered. This might be looked upon as almost a form of flank attack were it not that it differs from it in some essential particulars. The turning movement is more often a menace than an attack for it threatens the enemy's line of retreat so as to force him to change front or shift his position before he enters the combat. The manœuvre differs also from a flank attack inasmuch as it removes the scene of combat from the position held by the enemy, while the flank attack takes place on one of the flanks of the position itself. The turning movement may be made, either with a portion of the force at command, or with its whole strength. In the first case, the conditions should render it improbable if not impossible that the enemy could act offensively in turn upon each fraction of the divided force. Otherwise the separate movement should not be attempted, as it must end in disaster. When the ground permits, or is favorable, cavalry and horse-artillery should be especially utilized to the turning movement. They should, therefore, nearly always form a portion and sometimes the whole of the troops employed in the service, both because they can by rapid advance produce the moral effect of surprise, and because they can more easily avoid destruction by a superior force.

The commander of a small force of the three arms should have no difficulty in preparing his plan of attack and issuing his orders, upon receiving reports of the strength and dispositions of the enemy and of the nature of the ground upon which he must act. In ordinary cases when small forces are engaged, the cavalry, which reconnoiters in advance, will bring in sufficient information for the purpose; but if the enemy should be covered by advanced troops, it may be necessary to make a special reconnaissance, sometimes supported by guns, in order to arrive at a knowledge of his strength and intentions. With large forces this work must probably be carried out by the advanced guard the artillery of which, reinforced where necessary from the main body, would take up what may be called a preliminary artillery position and open fire at long range to cover the advance of the troops employed in the reconnaissance. The information required being obtained, the commander would issue his orders. In the case of very small operations or of a sudden encounter with the enemy these would be given verbally; under other conditions orders should, if possible, be written. Should these orders consist of detachments under various commanders, it would be necessary that there should be a general order for all, and also a special order addressed to each commander where separate action is required. The general order should be clear, precise and complete, and as short as quick compliance with these requirements will permit. It should contain:

1. The conditions or circumstances of the intended action with what is known of the enemy so as to guide the commander in determining the mode of action and the order in which the detachments should be sent in order to coordinate their efforts.

2. The mode of action determined upon, and how to be undertaken; thus for instance, to attack the enemy when he is touched on in direct advance, or, to attack the whole, or a certain part of a position.

3. The strength, composition and general division of the attacking force, with names of commanders; this may be given more in detail in the margin of the order if thought necessary.

4. The preliminary positions to be taken up by each distinct part of the force with their directions of attack.

5. The hours at which these positions are to be assumed, and at which the forward movement or attack is to be commenced.

6. The position where the commander of the troops will be found during the action, to which all references or reports are to be made or sent.

These clauses would be sufficient for a small force, but in operations of greater magnitude it would be necessary to add:

7. The positions of the ambulance and field hospitals, and the order of march of the trains of the various columns.

It must be understood that the dispositions of the troops thus indicated are only intended for the first phases of the engagement, for, until the enemy's counter-plans are developed, the final movements which depend thereon cannot be defined. The special orders addressed to separate commanders should contain nothing that may tie their hands too much in matters of detail. As a rule, they should be told the thing to do, not the manner of doing it, and within safe limits, to be named, they should be allowed free action.

For the purpose of watching the phases of the combat, the position which the commander should assume during the engagement ought, if possible, be on an eminence, from which he can perceive the principal portion of the ground over which the troops are to work. He should not quit this post (duly announced in the "order") without exceptionally good reasons, and if he is obliged to do so, an officer should be left behind to direct all reports or messengers to the new station of the commander.

The orders which are necessarily transmitted during an action by the commander of the troops are of much importance and should be given with great care. They should, if possible, be in general harmony with the original plan of attack, although certain modifications may become necessary. They should be concise but detailed which are better left to commanders of corps, nor should the commander of the troops interfere in the execution of his orders, further than to assure himself that they are carried out. He should be satisfied on this point by means of constant reports and communications which must be kept up without interruption during the action between him and the commanders of separate corps and detachments. When the reports cannot be sent by an officer of the commander of the troops, the reports of the latter in the exact hour and minute of dispatch. Above all other matters it is most important that the commander of the troops should be immediately informed when circumstances render it impossible for a subordinate commander to carry out the orders or instructions, as the failure
TACTICS

As the rule to be followed is, that it shall fire on that arm of the enemy which is for the time the most important, the enemy's infantry will in all probability be now the object. In either case, a moment may arrive during this stage when a second position more in advance is necessary for the guns, on account of their fire becoming masked by their own advancing infantry. If a portion or the whole of the guns can, in such case, be advanced rapidly and placed in a good position (especially on a flank, whence they can add their own fire to that of the advancing troops, which are at the moment absorbing the whole attention of the defending infantry), the proximity to the enemy's line, of this second principal artillery position, must not be too much limited by ordinary rules of caution. When the attack and defense are nearly matched, it is clear that the addition of a close artillery fire on either side may turn the scale and compensate by decisive success for any loss sustained. As this close action of guns may in case of repulse lead to confusion, it would perhaps be advisable that the whole of the available artillery should not take up this second advanced position, but that a portion be held in reserve, massed in a favorable position, and be kept in action all the time in support of the advanced battery.

If the attack is successful and the enemy retires either before the demoralizing influence of the last steady advance, or broken by actual assault, the position he occupied is quickly assumed by the artillery and a heavy fire brought to bear on the retreating troops. The reserve cavalry, which by this time has been brought up from the rear, and probably posted on the weaker flank is now launched in pursuit accompanied by horse-artillery, the superior mobility of both rendering their use peculiarly well suited to this service. The commander of the troops would move forward from his starting point, and take his develop fire-action should rapidly increase as the point of attack, for upon its weight depends its success.

cavalry on the flanks should be on the move as the infantry flanks own troops extended in the advance, but seize opportunities of approaching uns flanks of the opposing infantry or and of throwing them into disorderazing them, if not inflicting serious If repulsed and in its turn disordered, rally under the protection of other and again return to exercise similar

But cavalry at this stage can only minor part, unless the ground be more usually favorable to its action; with the on, therefore, of strong supports to the acting on the flanks, the remainder of would still be kept in reserve, but far to the rear that it could not be up quickly if required to make a demonstration on either flank artillery, which during the former has been of first importance on account of its long range, now falls into the sec. The circumstances of the case must be whether it shall fire on the enemy's troops, or whether it shall fire on the enemy's troops. As the rule to be followed is, that it shall fire on that arm of the enemy which is for the time the most important, the enemy's infantry will in all probability be now the object. In either case, a moment may arrive during this stage when a second position more in advance is necessary for the guns, on account of their fire becoming masked by their own advancing infantry. If a portion or the whole of the guns can, in such case, be advanced rapidly and placed in a good position (especially on a flank, whence they can add their own fire to that of the advancing troops, which are at the moment absorbing the whole attention of the defending infantry), the proximity to the enemy's line, of this second principal artillery position, must not be too much limited by ordinary rules of caution. When the attack and defense are nearly matched, it is clear that the addition of a close artillery fire on either side may turn the scale and compensate by decisive success for any loss sustained. As this close action of guns may in case of repulse lead to confusion, it would perhaps be advisable that the whole of the available artillery should not take up this second advanced position, but that a portion be held in reserve, massed in a favorable position, and be kept in action all the time in support of the advanced battery.

If the attack is successful and the enemy retires either before the demoralizing influence of the last steady advance, or broken by actual assault, the position he occupied is quickly assumed by the artillery and a heavy fire brought to bear on the retreating troops. The reserve cavalry, which by this time has been brought up from the rear, and probably posted on the weaker flank is now launched in pursuit accompanied by horse-artillery, the superior mobility of both rendering their use peculiarly well suited to this service. The commander of the troops would move forward from his starting point, and take his develop fire-action should rapidly increase as the point of attack, for upon its weight depends its success.

arms decide to stand on the defensive, he should take up the position most suitable for his purpose without delay, as the superiority to be attained by this course of action must result in great measure from the advantages attendant upon choice of ground. A good position should be such, from a tactical point of view, that the different arms could be disposed for defense in the manner most suitable to their action and that there should be facilities for concealing their strength, composition and posts from the view of the enemy, and of preserving them more or less from his direct fire during the attack. It is also of the highest importance that the front of any position selected for defense should be clear for view and fire, as should also be the flanks, unless they rest on impassable obstacles.

The first stage of the defense which was commenced with the reconnaissance of the enemy would thus comprise the selection and occupation of the position by the defenders, as well as the advanced action, if any, of the artillery, already alluded to. Upon the selection of the ground most suitable for the artillery of the main position, will in great measure depend the exact trace of the fighting line for the infantry, the positions for the guns so much depending upon the circumstances of each case, and more especially upon the configuration of the ground. The guns of the position should, however, be placed so as to bring the enemy's columns under fire at long range, and hence they ought to command every distant approach. They should also be able to pour a concentrated fire upon the probable positions which will be assumed by the attacking artillery, and be stationed so as to sweep the ground in front of the position from the earliest to the latest moment of attack. The defense of the flanks in the case of large forces must be specially provided for.

It would, therefore, appear that, unless the ground is peculiarly favorable for posting guns in flanking positions, where without being exposed to enfilade they can bring a cross fire to bear upon the main attack, and a flanking one to protect the immediate front, the required command can only be obtained by the guns being placed in the front line and preferably at the salients, should an irregular contour mark the front of the position. The general distribution of the infantry would probably be in three lines; the first or fighting line of defense, the special supports, and the reserves. If time for hasty fortification is permitted some sort of entrenchment should be always prepared for the batteries, as even a low parapet of earth gives protection to the gunners. Great care should, however, be taken that the newly broken earth is concealed or covered in such a manner from the enemy's view, that it shall not serve as a mark for their artillery more distinct than would otherwise be presented by their guns alone. Shelter-trenches may also be prepared for the infantry in the fighting and supporting lines. Neither the places prepared for the batteries nor the shelter-trenches should be occupied by the guns or troops till the proper moment for action arrives.

Advanced skirmishers or marksmen, and with this view, the batteries ought to be covered in their immediate front by a line of extended skirmishers, placed either in trenches or pits or behind natural cover, and from four to five hundred yards in advance of the guns which they defend. If the battery is on a flank, this protection should also be extended for a similar distance to the flank. The infantry thus posted would remain as long as possible in position, and only retire when, at the final stage, they are driven back by the overwhelming advance of the assailants. Besides their principal function, of keep-off the enemy's skirmishers from too early approaching, the batteries of the defense, these advanced infantry could often bring an irritating fire to bear upon the attacking artillery at its first principal position, and perhaps serve to prevent the guns from approaching to the most telling range. This possible action would of course depend much upon the features of the ground.

It is impossible to lay down any rule for the exact position of the artillery of reserve. High ground near the exposed flank, provided facility of movement therefrom in case of necessity is present, and if the features would often be suitable. The guns should, however, in any case be well up to the front, so as to lose no advantage of range from the commencement of their fire. A position in rear which entails would not be comparatively useless during the later stages of the defense, when once the attacking infantry has advanced so close that the fire of the retired batteries would be masked by the ground, or by the defending infantry lining the position. Guns so placed might be useful in defending an inner line, or for supporting a counter-stroke delivered inside the position after the assault has been made, their action would be lost almost altogether during the period immediately preceding the final assault if not by the position itself or by knowledge of ranges and distances, possible to the artillery of the defense, presents a great advantage; but if circumstances have not permitted the gunners to ascertain them during the preliminary arrangements, by aid of rangefinders, aeroplanes, or other means, the earliest portion of the artillery action must be utilized to obtain correct estimates of the ranges to all important points, by means of trial shots.

There are certain points or portions of all positions, the possession of which would assure the assailant the greatest tactical advantages. In many cases also the configuration of the ground appears to limit the movements of an enemy to certain lines of operation. The defense should, therefore, occupy these parts of the position, not by force, but by assumed or apparent force by the enemy, while preserving the general line. Under the second condition the force should be prepared to resist advance by rapid reinforcement at any of the possible points of approaches. The force in the third line should be placed so as to be available for strengthening the most likely points of attack and to be advanced skirmishers or marksmen; and with
TACTICS - TADOUSAC

protect the line of retreat. Most of the and some horse-artillery if it can be used will fulfill the reserve. It is very well placed for opening fire, and the reserve is in position if needed for the reconnaissances. A portion of this force is placed on the right for the purpose of joining in and ranging movements and flank attacks upon the left, and of covering the retreat of the engaged in these counter-attacks if unf avorably. The second stage generally commences with opening fire at long range from the batteries of the system, upon the heads of the enemy's infantry to give it order of...and deploy the artillery. The attacking artillery will reply now from its principal position as the artillery of the attack is at the most important arm it must be used by the guns of the defense. In artillery duel the defenders should have ample time, as knowing accurately the ranges of various points which must be occupied by the enemy in his advance, and as being more entrenched while the assailants are all at the mercy of the firing of the artillery of the defense are brought to the position and open long-range fire upon the enemy with more or less effect. The third stage the advance to effective range of the attacking infantry has forced...the direction in which it is object of the defending commander over, by every means in his power. As ports and reserves of the assaulting...farmers, the concentrated fire of part of the defense. The fourth stage the real point menaced attack being made clearly apparent, the...in the enemy, now has become the principal arm in the attack. Should a counter-attack be probable, it takes place during this stage, unless it is delayed until after the assault. The...to a flank movement of the attacking force would also now have to be made. It is of a counter-stroke being delivered defense, part of the cavalry and heavy...finally, it should generally move forward flanks at this part of the action to seek opportunities of throwing the flanks of attacking infantry into disorder, or of taking too rashly advanced. The fifth or last stage comprises the final of the attack upon the position or the forces' enforced retreat therefrom. In case pursuit by the victors may ensue, lately and during the final assault, every gun of the defense will concentrate its fire upon the attacking forces, in order to check their advance, and the assailants retire, the guns must continue to fire until the assaulting troops are sent forward in pursuit. Should...on the other hand, be forced to attack, guns must cover the movement and the infantry to disengage itself. The underlying idea of all infantry tactics must be to bring into action with all the units well in hand. The ideal of the men would be those making possible a quiet, quick and orderly advance without halting to open fire, but this is impossible with the highly developed weapons of today. However, though some of the attacking infantry managed to close with the enemy, there would be too few left for a bayonet attack. Therefore, in order to make a successful assault, the infantry must move up under covering fire. To provide cover for this protection, it has equipped itself with the pistol, bayonet, fire, the one-pounder, trench mortars, the effective hand and rifle grenades, and has called to its assistance its supporting arm—the artillery. The enemy, attempting to protect himself from the terrific fire, he knows will precede the infantry attack, has prepared deep dugouts and bombproofs, in which he often hides until the last possible minute.

Despite the fact that all of the above preparations are simply to give the bayonet man a chance to use his weapon (and to kill as many of the enemy as possible while doing it), it follows that fierce action is more important than shock action, for without the fire the shock would be impossible. Therefore, the bayonet men must know how to shoot their rifles and to co-operate with the machine gun, the grenade, and the artillery, and must be so formed that during the assault they can deliver effective rifle fire, present a solid front to the enemy in the bayonet charge, and be close enough to furnish mutual moral and physical support. The wave attack that has been used so much in France was produced in order to furnish the greatest amount of mutual support among automatic riflemen, grenadiers, the one-pounders and riflemen, and at the same time to allow the greatest number of riflemen (bayonet men) to close with the enemy in the best formation possible. All of the conditions so far discussed make it imperative that the assaulting troops be perfectly organized and that they follow their covering fire (barrage) as closely as possible.

EDWARD S. FABOW, Consulting Military and Civil Engineer.

TACTICS, Naval. See NAVAL TACTICS.

TACUBAYA, tā-koo-bā'yā, Mexico, a city in the federal district, situated three miles southwest of Mexico City, is a principal pleasure resort of the valley of Mexico, and has many fine buildings and gardens. The national observatory is situated here, as well as the castle of Chapultepec. Pop. about 40,000.

TACULLI, an American Indian tribe of the Athapaskan family, residing in British Columbia, at the headwaters of the Peace and Fraser rivers. They numbered about 750 in 1918 and lived on various small reservations. The majority of them are Roman Catholics, having been converted by French missionaries.

TADEMA, tā'dē-ma, Laurence Alma. See ALMA-TADEMA, LAURENCE.

TADOUSAC, tā-doo-zik', Canada, a town in Chieoutimi and Saguenay County, Quebec, situated at the confluence of the Chicoutimi River with the Saint Lawrence. It is a summer resort; and noted as being the oldest settlement in Canada. It was one of the early centres of the fur trade, and the home for a time of Father Marquette, who developed the weapons of to-day, and was visible one of the early Jesuit establishments. Pop. 2,500.
TAPOLES—TAFT

TAPOLES. See Fogo.

TAFILET, tā-fē-lēt', or TAFILELT, Morocco, an oasis on the southern border of Morocco and northwestern border of the Sahara region, 200 miles south by east of Fez. It covers about 530 square miles, and has a population of about 5,000, distributed among about 150 villages, of which Aumam is the most important. The date-palm is cultivated, and silks and rugs are manufactured.

TAFT, Alphonso, American jurist: b. Townsendh, Vt., 5 Nov. 1810; d. San Diego, Cal., 21 May, 1892. He was appointed judge of the Superior Court of Connecticut, serving until 1872, when he resigned to resume his law practice. On 8 March 1876 he was appointed by the war to the post of Attorney-General. During 1877–82 he was engaged in practice in Cincinnati, and in April of the latter year was sent as Envoy Extraordinary and Minister Plenipotentiary to Austria. From 1884 to August 1885 he was Minister to Russia.

TAFT, Charles Phelps, American lawyer and statesman; half-brother of President Taft: b. Cincinnati, Ohio, 21 Dec. 1843. He was graduated at Yale University in 1864, and later studied at the universities of Heidelberg, Berlin and Paris. He was admitted to the bar of Ohio in 1866 and in 1869–70 was engaged in practice in Cincinnati. In 1879 he became the principal owner of the Cincinnati Times which in 1880 he consolidated with the Star as the Times-Star, of which he has since been editor. He was a member of the Ohio House of Representatives in 1873 and served in Congress in 1895–97. He was presidential elector-at-large from Ohio in 1904, and president of the Ohio electoral college in January 1905.

TAFT, Henry Walters, American lawyer, brother of President Taft: b. Cincinnati, Ohio, 27 Jan., 1846. He was admitted to the bar in 1868 and later studied at the Cincinnati and the Columbia Law Schools. He was admitted to the bar in 1882 and engaged in practice in New York, where he is a member of the firm Cadwalader, Wickersham and Taft. He was special assistant to the Attorney-General of the United States in the tobacco trust investigation. He was a member of the New York board of education in 1896–1900; a trustee of the College of the City of New York in 1903–05; and since 1908 has been a trustee of the New York Public Library. In 1907 he was appointed chairman of the Permanent Legal Advisory Board for Greater New York under the selective service regulations.

TAFT, Lorado, American sculptor: b. Elmore, Ill., 22 Dec. 1871; and studied at the University of Illinois (1892–93), later at the University of Illinois (1897–98). He opened a studio in Chicago in January 1896; from 1896–1907 was instructor and since lecturer at the Art Institute of Chicago. He has since lectured at the University of Illinois (1892–1902) and since 1902 has been professor of the history of art. He won the medal at the Columbian Exposition (1893); silver medal, Pan-American Exposition, Buffalo (1901); gold medal, Pan-American Exposition (1904). His lectures exercised a wide influence: he received the honorary L.H.D. from Northwestern University; of 'The History of American Sculpture,' from the Board of Education; of 'The Eternal Silence,' from the University of Chicago; of 'Solitude of the Soul,' from the University of Michigan; of 'Blackhawk,' from the University of Nebraska; of 'Washington,' from the University of Washington; of 'The Great Lakes,' from the University of Ohio; of 'Soldiers' Monument, Indianapolis;' from the University of Indiana; of 'Ogle County Soldiers' Monument,' from the University of Illinois; of 'The Chicago Memorial Fountain, Denver; Cole' from the University of Pennsylvania. He has since lectured in several universities.

TAFT, William Howard, 27th Pres. of the United States: b. Mount Pleasant, Cincinnati, Ohio, 15 Sept. 1857, son of Judge and Louisa M. (Torrey) Taft; graduated with honors from Yale; studied law in Cincinnati, Ohio, and for a time Collector of internal revenue at Cincinnati. He was a native of Cincinnati, and after 1885 being county solicitor, in 1886 he married Helen Herron. In 1887 Governor McKinley appointed him to fill an unexpired term of the Superior Court. He was later Solicitor General of the United States, and in 1892 he was appointed solicitor-general of the United States. In 1892 he was made judge of the Sixth Circuit, a position for which he was fitted, and the work of which he was congenial.

On 12 March 1900 President McKinley asked him to head a commission to establish government in the Philippines, and on 1901 he became first civil governor. He copied both appointments at the expense of his personal preference for a career in politics, being influenced by a deep sense of responsibility toward a genuine affection for Filipinos. In 1902 Roosevelt twice an appointment to the Supreme Bench of the United States, but his rank and degree in his chief personal ambition, his immediate duty was to continue in the Philippines. As an executive his work was highly successful. In 1902 he conducted at Rome the negotiations for the purchase of the Friars' lands, but his rank and degree in his chief personal ambition, his immediate duty was to continue in the Philippines. As an executive his work was highly successful. In 1902 he conducted at Rome the negotiations for the purchase of the Friars' lands, but his rank and degree in his chief personal ambition, his immediate duty was to continue in the Philippines. As an executive his work was highly successful.
before they would be ready for self-government. He believed in "The for the Filipinos," and opposed extension in the interest of American urged tariff concessions for Filipinos.

In 1904 he became Roosevelt's Sec-

Vice-President, and for over four years was successively in the United States, and in the Panama Canal. In 1906, when called for American intervention, he went to Cuba, and for a time acted as governor. In 1907 he visited Cuba, and later Japan and China, going to the Philippines for the opening of the legis-

bly, and returning by way of Russia on 06–13 he acted as president of the American Red Cross.

Roosevelt was exerting his influence the Republican nomination for his own War, whom as post-

standard of absolutely unflinching service in every point of public duty, and a lacking courage and willingness toubs;

2. The President declaring that Taft

ian who I feel is in an especial senseOmtative of all that in which I most political life."

l on the strength of his ideal train-

ance. Taft was given 321 electoral ryan's 162.

sident lacked the magnetism and orce of his predecessor. In general moderate position on public questions. e-of-the-road people," he said (1911), not extremists are, we believe, the essives, because you do not make y great strides; you make progress p."

His position on important issues summarized as follows: (1) In con-

the Post-Aldrich Tariff Bill. The influence in favor of downward revi-

protective basis, just sufficient to difference in cost of production be-

and abroad. Though not satisfied provisions, he signed and defended ever passed. He favored vision on the basis of reports to be a tariff commission; and he vetoed ones of several schedules largely be-

were not based on such reports.

1 for reciprocity with Canada. (2) vation his fundamental views were erent from those of the Progressives med to believe. He hesitated, how-

reached the executive power, and Con-

solidated it; gave him the power he re-

Unfortunately his support of Secre-

inger against Roosevelt's friend, appeared to place him in opposition to s of his predecessor. (3) In the

broad and trust regulation he dict enforcement of existing law and stration secured the dissolution of ard Oil and Tobacco trusts. He clarification of the Sherman law and dustry that was doing business. (4) He was opposed to radical schemes of direct popular

government, in particular the recall of judi-

cial decisions. (5) He favored and extended civil service reform, worked for efficiency and economy in government, especially urging a budget system and advocating pensions for Federal employees. (6) In foreign affairs he worked heartily for peace, negotiat-

ting treaties for arbitration and the judicial settle-

ties, which were rejected by the Senate. By "dollar diplomacy" the administration sought to secure opportunities for trade and the investment of capital. This policy was denounced by some as leading to imperialistic interference in the affairs of weaker nations, and making government diplomacy a mere agent of big business.

Some of these views were too progressive to suit the old leaders, and yet it was not long before the insurgent Progressive-Republicans were denouncing the President as too friendly with reactionary party bosses and big business, and a deserter from progressive standards. Believing in the necessity of party government, the President did feel it necessary to work with and through the party machinery in promoting his policies. For a time he withheld patronage from insurgent senators and representatives, and when he changed his policy the damage had been done. The defense of the Tariff Bill, the dismissal of Pinchot, the repeated vetoes of later tariff reduction bills, the veto of the grant of statehood to New Mexico and Arizona because of radical provisions in their constitutions, all increased his unpopularity. The elections of 1910 gave the Democrats a majority in Congress and showed a popular discontent with the old Republican rule and a drift toward Progressive Republicanism or toward the Democratic party. In Congress the insurgent Republicans often joined the Democrats to defeat the regular Republicans. In 1910 Roosevelt returned from a trip to Africa, and before long was openly taking issue with the policies of his successor. By 1911 the Progressive Republicans were planning to prevent the renomination of Taft. At first La Follette was to be their candidate, then they turned to Roosevelt. Early in 1912 he agreed to accept the nomination. In the States having direct primaries Roosevelt made a much better showing than Taft; but the control of the party machinery by the regulars brought about the President's renomination. The Progressives started a new party, ensuring the overwhelming defeat of the President in November and the election of Wilson.

The outstanding feature of the administration was the conflict between conservative and progressive forces; but the confusion and recrimination should not obscure important developments during these four years. Among these were the reform of the rules of the House of Representatives (1910); the Corporation tax (1909); increased powers of the Interstate Commerce Commission; Postal Savings Bank (1910) and Parcel Post (1912); Children's Bureau (1912) and Department of Labor (1913); publicity for and limitation of campaign contributions on income tax and direct election of senators.

Since 1913 Mr. Taft has been Kent pro-

fessor of law at Yale University, lecturing on constitutional law in the college and the law school. He has continued to take an active
interest in promoting international peace and a League of Nations. During the World War he was joint chairman of the National War Labor Conference Board.

With the calming of factional bitterness, Mr. Taft has gained again in the public esteem and confidence, and the accomplishments as well as the mistakes and difficulties of his administration appear in a better perspective.

ARTHUR P. SCOTT,
Assistant Professor of History, The University of Chicago.

TAGABAWAS, tā-gā-bā'-vās, a Philippine people living on both sides of Dávao Bay, Mindanao, a mixture of several Malay tribes.

TAGACAOLOS, tā-gā-kā'-o-lōs, a Philippine tribe, whose settlements are scattered among other tribes along Dávao Bay, Mindanao.

TAGALS, tā-gāl's, TAGALOOS, or TAGALOS, a Philippine people of Malay origin, inhabiting chiefly Mania, the provinces of Cavite, Batāán, Bulacán, Batangas, Infanta, Laguna, and Mindoro, and scattered among other tribes in several other provinces. They are Christians and one of the leading peoples of the archipelago, both in numbers and in culture; they possessed an alphabet and considerable civilization before the arrival of the Spaniards. They were the leading element in the last insurrection against Spain, and proved troublesome after American occupation. They are, however, intelligent, shrewd and generally industrious; and when once comprehending American ideas prove trustworthy. See PHILIPPINE ISLANDS.

TAGANROG, tā-gān'-rōg', Russia, a town in the government of Ekaterinoslav, on a lofty promontory on the Sea of Azov, opposite the mouth of the Don, 28 miles west-northwest of Azov. There is a monument to Alexander I, who died here; also churches, exchange, gymnasia, etc. It has manufactures of candles, leather, tobacco, macaroni, etc. The harbor, though the deepest in the Sea of Azov, is shallow, not admitting vessels which draw more than 10 feet; but its situation secures to it a considerable trade. The principal exports are wheat, rye, barley, oats, linseed, rapeseed, wool, oil, fish, flour and butter; the imports include fruit, oil, machinery, hides, petroleum, dry goods, wine, etc. The annual exports previous to the World War averaged over $50,000,000. Pop. 71,000.

TAGBANUAS, tāg-bānoo'-as, native tribes of the Philippine Islands inhabiting the island of Palawan. They may be classified into five groups, some more civilized than others, according to the nature of the locality and the extent of contact with the coast tribes. The Tagbanuas Apurahmuos have a peculiar writing and alphabet. They have an elaborate system of laws for the regulation of morals and 'fast days. Their god is Diwata, the protector and representative on earth of the Balahan, who may be either a woman, Vincemó, M. H., 'Man and Cat Creators of the悬挂s and Other Tribes of the Island of Palawan, Philippines,' in Journ. Amer. Micr. and Miscellaneous Collections,' Vol XI 1907, 84 pp, Washingto, 1907.

TAGBILARAN, tāg-bē-lā-rān, Philippines, pueblo, capital of the province of Bohol; on the southwest coast. Opposite the town is the important dependent island of Panglao, separated from Bohol Island by a strait one mile in width. The chief industries are agriculture and turtle fishing. Pop. 11,000.

TAGESS, tā'-jēz, in early Italian mythology, son of a minor local deity, or genius, and grandson of Jupiter. He taught the arts of augury and divination, and was said to have sprung forth from a cloud of earth freshly turned up by a husbandman named Tarchon, in the neighborhood of Tarquinii.

TAGGART, Marion Ames, American writer for young people: b. Haverhill, Mass., 7 May 1866. She has published 'The Blissylvania Post Office' (1897); 'Aser, the Shepherd' (1899); 'The Wyndham Girls' (1902); 'In the Days of King Hal' (1902); 'Nut-Brown Joan' (1904); 'Pussy Cat Town' (1906); 'Betty Gaston' (1910); 'Nancy the Doctor's Little Partner' (1911).

TAGGART, Thomas, American congressman: b. County Monhyan, Ireland, 17 Nov. 1836. He came to the United States in 1861 and settled at Xenia, Ohio. He engaged in the hotel business at Indianapolis in 1877, and since 1886 has been active in politics. He was chairman of the Democratic State Committee in 1892-94; mayor of Indianapolis in 1895-1901; and in 1916 was appointed to fill the vacancy in Congress caused by the death of B. J. Snively. He was elected to Congress in 1912 and in 1914.

TAGISH, a tribe of American Indians formerly residing about the headwaters of Lewis River, Alaska. A remnant of the tribe still exists.

TAGLIONI, tāl'-yō'-né, Maria, Italian ballet dancer: b. Stockholm, Sweden, 23 April or 18 March 1804; d. Marseilles, France, 23 April 1884. Her father was Filippo Taglioni (b. Milan, 1777; d. 1871), a ballet master at different opera-houses successively in Europe. She was rigorously trained by her father and developed a marvelous grace, so that she became the admiration of Europe in her day. She made her début at Vienna in 1822; appeared at Paris in 1827, and at Berlin, London, and other capitals later. Her style was termed 'ideale'; was chaste and refined in distinction to the 'realistic' dancing of her predecessors, Gardel and Vestris. Her great successes were 'La Bayadère,' 'La Sylphide,' composed for her by her father, and 'La Fille du Danube.' In 1832 she was married to Count Gilbert de Voisins, and in 1847 retired from the stage. She is frequently mentioned in contemporary literature, particularly by Balzac and Thackeray.

TAGORE, tā'-gōr, Sir Rabindranath, Hindu poet: b. Calcutta, 1861. His father Maharshi Devendranath Tagore was a famous spiritual leader who helped to distinguish for many generations throughout India. He was educated chiefly under private tutors and at the age of 17 visited England. By this time he was writing verse, largely imitative of the old Vaishnavite. When he was 18 years old he published 'Sandhya-Sangita' (Songs of Sunset), and 'Pravata-Sangita' (Songs of Sunrise). In these he aims to the height of neo-romanticism in Bengali poetry. In 1864 he was married and went to
TAGUS — TAHEQUAH

in the banks of the Ganges to manage his estate. There he came into touch with the life of the people and wrote poems, always telling dramatic tales of their affairs. His best known works of verse are 'The Crescent Moon,' 'Gitanjali,' 'A Home in the World,' and 'The Hungry Child.' This second or third period of his life, which lasted 17 years, was a period of great happiness and succeeded quickly death, his wife, daughter and the son of his two sons. At the age of 40 he began work at Bulpur, which centred in school, 'Shanti Niketan,' or a transitory phase of life. He was the first of two boys it had grown in four years to 20 boys by 1919 numbered over 200 boys, while strictly Indian in its character, embodied in itself, in forms modified by the influence of the world to-day, while also the best traditions of the ancient and the modern schools. It is interesting to note that the self-governing students are rapidly diminishing in number and that the chief exports, whose value in 1902 amounted to $800,000. Papeete, on the northwest coast, is the French administrative capital for all the French possessions in Polynesia. The native Tahitians were once a splendid race, noted for their simple, idyllic life. (See TAHITIAN LITERATURE.) The vices introduced by contact with civilization soon brought about moral and physical degeneration, and the native inhabitants were rapidly diminished in numbers. The island was discovered by a Spanish navigator, Quiros, in 1605, and visited by Captain Cook in 1769. In 1842 it came, as a native kingdom, under French protection, and in 1880 was declared a French colony. Pop. about 12,000. See SOCIETY ISLANDS.

TAHITIAN (tā-hē-tān) LITERATURE.

As mentioned under Tahiti, the natives of this southern Pacific island were once a beautiful race, living a natural, simple and idyllic life, as expressed in the accounts of Tahiti by Wallis, Bougainville, Cook and others, and idealized in the works of Melville, 'Omoo' (The Rover); Stoddard, 'Idylls'; and Loti, 'Marriage.' Notwithstanding their physical and moral degeneration since the introduction of European civilization, the evidences of the primitive state of existence, outside the region of early explorers, are to be found in their traditions and legends preserved in the native songs and poems of the existing Teva family, of royal lineage, descended from Hototu, first queen of Vaiere, who married a European, the first king of Punaia. The songs, generally of love, war and lamentation, locally called hīmenes, are sung as a kind of choral chant with a monotonic buzzing bass, on which a high shrill cadencing is repeated indefinitely, holding always in a long ile-i-e-e. The longer poems recite the history of the family, the various forms of etiquette and addresses for visits; shorter poems consist of soliloquies, laments, reproofs and ceremonial topics. Among favorites of which English translations have been made are the 'Coronation Song of Pomare'; 'Lament of Aromaiarai'; 'Soliloquy of Tcura, a beauty asked to wed Punu, an old chief'; and 'Song of Reproof, at the beginning of the Wars between Teva and Puni, in 1768.' Consult La Page, 'Tahitian Literature' (p. 1439, Vol. XXIV); 'Warner's Library of the World's Best Literature.'

TALEQUAH, tā-lē-kwā', Okla., town, former capital of the Cherokee Nation, in the valley of the Illinois River, about 18 miles east of Fort Gibson, and 25 miles north of Muskogee, on the Saint Louis and San Francisco Railroad. It is in a fertile agricul-
tural region. It contains two public high schools, the Cherokee National Female Seminary and the Cherokee National Male Seminary. The latter was founded in 1847. There are two mission schools, the Baptist and the Presbyterian, and two school libraries. There is one bank and four weekly newspapers. The manufacturing is increasing, and there are grain elevators, cotton gins and flour mills. Pop. (est.) 3,000.

TAHOE, tâ-hô', a lake in the base of the Sierra Nevada, on the boundary between California and Nevada, part in Placer County, Calif., and part in the counties of Douglas and Ormsby, Nev. It is about 20 miles long and from 8 to 12 miles wide, and has an altitude of 6275 feet, and an extreme depth of 1,650 feet. The outlet is Truckee River. Lake Tahoe is noted for its beauty and the picturesque surroundings. It is a favorite and unique summer resort, on account of the cool and healthful climate and the beautiful scenery.

TAHIPANIES, or TEHAPNEHES, an ancient city, mentioned in the Bible (Jer. ii. 10; xiii. 7), usually identified with the Daphne of the Greeks, situated in the north-eastern part of the Delta, about 30 miles south-west of Pelusium. In 1886 the site was explored by Petrie (q.v.), who gives an account of his work in his 'Tanis,' Part II (1887).

TAHR, târ, a wild goat (Hemitragus jemnalaus), found on steep tree-covered slopes along the whole range of the Himalayas from Kashmir to Bhutan. The horns are about a foot long, flattened, with a notched anterior margin; body fawn-brown; the hair of the neck, chest and shoulders hangs to the knees; the female is lighter in color with smaller horns. Its nearest relative is the nigher goat of central India.

TAI-CHU, tî-chou', the former capital of Formosa (q.v.). See TAINAN.

TAI-NGNAN-FU, tîn'gân-fou', China, a city in the province of Shantung, situated 35 miles north-west of Tai-nan, on the railway to Yichau. It has a temple covering a large area, which draws many pilgrims bound for Mount Tai, which is regarded as sacred. Pop. about 75,000.

TAI-TOU, empress of Abyssinia: b. 1853; d. Addis Ababa, 11 Feb. 1918. She was a daughter of the king of Gondar and took an active part in the troublous politics of Abyssinia, and was concerned in all the civil wars and intrigues which ended in the raising of Menelik, whom she had taken for her fifth husband in 1853 when he was simply king of Shoo, to the position of Negus-Neqgusti (emperor) in 1889. At Adowa where the Italians suffered a crushing reverse, she accompanied Menelik to battle headquarters and put her own hereditary troops in the field. During Menelik's long illness she practically governed the country and kept it from internal disorders. On Menelik's death in December 1913, his grandson, Lidj Jassan, a youth of 18 and no blood relation of the empress, became emperor, but failed to maintain order, and largely on this account he was deposed in September 1916, and his aunt, Zauditu, Menelik's older daughter, was proclaimed empress.

TAI-YUAN-FU, tîwán'foo', Chin capital of the province of Shan-si, situate the centre of the province, 260 miles south of Peking. It consists of a Chinese and a Christian section, separated by a high wall. It served as the residence of the emperors and contains a number of magnificent mausoleums. The surrounding region is very fertile and contains rich coal deposits. Pop. over 200,000.

TAIHKOU, Formosa, capital of the It has progressed rapidly since it came under Japanese government in 1895. Systematization was begun in 1919, and in 1919 population was over 100,000. See Formosa.

TAILFER, Patrick, American who lived in the 18th century. He was a pen and emigrated to the newly-founded colony of Georgia in 1740. Later he returned to Connecticut. He is remembered for his authorship of a 'True and Historical Narrative of the Colony of Georgia from the Settlement thereof Until the Present (1741). It is a severe arraignment of James Oglethorpe, the founder of the colony and accuses the general of undue cense of arbitrary authority and of putting personal interests before those of the colony. The work has been the subject of much discussion as to whether it was justified, but it is merely the expression of a group of settlers.

TAILLON, Sir Louis Olivier, Canadian statesman: b. Terrebonne, Quebec, 26 April 1840. He was educated at Masson College, which was called to the bar in 1865. He engaged in practice at Quebec in 1882 and became the leader of the bar. He served in the House of Commons from 1875; was speaker in 1884; Attorney-General in 1884-87; and in 1887 he formed an administration. In 1890 he resigned his seat in the House of Commons after his retirement to private life.

TAILOR-BIRD, an East Indian species of Orthotomus or Sutoria sutorius), one of a genus which exhibit a similarity in structure and habits. The habitat cultivated districts, are dressed in tints, fed chiefly on insects, and are partly in their nest-making. They either dead leaf to a living one or join two boring leaves together, so as to form a hanging pouch, which remains attached to the branch by the leaf-stalk of one of the leaves. The threads which they use are generally of twisted vegetable fibres or natural cotton threads, the bill serving for a in puncturing holes in the leaves and inserting the threads through. Occasionally a large enough leaf be found, the nest a common thing. Two threads are inserted into the leaf. The lower part of the pouch contains the nest, which is a cup of soft moss and is entered from above. The actual ture of this ingenious cradle have not been scientifically observed, although it is certain. The best information is cot to in Humen. 'Nests and Eggs of Indian (London 1890) .
TÁIN BÓ CÚALNGE, THE CUALNGE CATTLE-RAID

The medieval Irish scholars catalogued their native literature under several heads, to one of which they gave the name Táin, by which they meant a "revenge" or "redemption of cattle." The most important tale belonging to this class is the subject of this article. The professional Irish story-tellers also arranged their epic tales according to cycles, one of which was known as the Ulster cycle. This cycle corresponds in a remarkable way to Ulster as the cycle of Conchobar (Connor), the king round whom the Ulster warriors mustered; as the Red Branch cycle, from the name of their banqueting hall; and, finally, as the Cuchulainn cycle, from the name of the champion round whom the saga pivots. The 'Táin Bó Cúalnge' has always enjoyed the reputation of being the most celebrated story of Irish antiquity.

The following is the argument of the Cualnge Castle-Raid. Cuchulainn arranged between Queen Medb of Connaught and her husband, Ailill, as to the amount of their respective possessions. On matching their wealth, they were found to be equal, except that among the king's herds was a lordly white bull called "the White Bull". Medb dispatched her courier to Daré mac Fiachna, a rich landowner in Cualnge (Anglicé Cooley), in Ulster, to ask for the loan of his wonderful bull, called "the Brown of Cualnge." Daré at first granted the queen's request but, incensed at a remark made by one of the envoys, he withdrew his promise and swore that he would hang over the Brown Bull of Cualnge.

Medb straightway gathered a formidable army composed of allies from all parts of Ireland wherewith to undertake the invasion of Ulster and to carry off Daré's bull by force. Now it happened that the expedition took place while the Ulstermen suffered a debility which lasted all winter and the burden of defending the province fell on the shoulders of a striping of 17 years of age, namely Cuchulainn, who was exempt from the curse which had befallen the remainder of the champions of Ulster.

Cuchulainn confronted the foe and agreed to allow them to continue their march on condition that every day they send one of their champions to meet him in single battle. When he shall have killed his opponent, the host shall halt and pitch camp until the following morning. Queen Medb agrees to abide by those terms. In each of the combats which ensue, the heroic youth is victorious and slays many of the most celebrated warriors on the side of Connaught. The severest of all those single fights was the one which lasted four days and in which he had as antagonist his early friend and foster-brother, Ferdiad. After the death of Ferdiad, Queen Medb, impatience with having to always have of ancient Irish warfare and overran Ulster with fire and sword.

By this time the Ulstermen have come out of their debility and gathered their forces. In the face of a work of art like the 'Cualnge Cattle-Raid,' it is not a finished epic, but an epic in the making, showing better perhaps than any other work in literature the development of popular tradition through more than a thousand years and the earlier stages of an epic. It affords a picture of "an old barbaric civilization," with

Irish annalists about the time of the birth of Christ, that is to about 300 years before the introduction of Christianity into the island, and such has been the constant Irish tradition. It belongs to a period when agriculture was little known, although the possession of land to place upon it was of first importance and when cattle-raids were of frequent occurrence. The general condition of culture described in the saga corresponds with that part of the age to which archaeologists have given the name La Tène, or Late Celtic, and which terminated at the first century of our era.

The 'Táin Bó Cúalnge' even carries us back to one of the earliest and most widespread beliefs of the great linguistic family to which we belong, to one of the most primitive aspects of a world-wide nature-myth. Its great protagonist, Cuchulainn, is the incarnation of a god, who appears to personify warmth and light struggling against the powers of cold and darkness. In the earliest version of the story, he is the son of the supreme god Lug and a mortal woman. Hence the curious combination that we find on the one hand he acts like a brave and courtly warrior; on the other, his supernatural exploits exceed the course of ordinary human existence. By the time the tale had been given an historical framework and had been consigned to writing, the mythological idea from which it had sprung was, at most, but dim and uncertain. The story-tellers and their hearers regarded Cuchulainn and the other characters of the saga as real Irish men and women, and, although we are not to look for historical accuracy in the saga in every particular, it is very likely that, in the main, the events narrated really took place and the protagonists really existed.

The whole spirit of the 'Táin Bó Cúalnge' is strongly pagan, which is another proof that the tale was committed to writing very early in the Christian period. It is not the work of any one man, but the epic of all Ireland, the accumulated work of generations, the last stage of a slow evolution. The literary form may have taken place as early as the 5th century and its shaping, substantially as we have it, dates from the first half of the 7th century, if not earlier. The earliest manuscripts containing it probably disappeared during the Viking invasions, with the result that the oldest extant version dates from the year 1100. From that date till the middle of the last century a score or more of manuscripts have preserved it. Consequently, the 'Táin Bó Cúalnge' is the most ancient epic tale of western Europe and its composition antedates by a wide margin the epic tales of the Anglo-Saxons, the Scandinavians, the Franks and the Germans. Furthermore, it is entirely original and contains not the slightest hint of any foreign derivation.

The 'Táin Bó Cúalnge' is in prose interspersed here and there with verse and is not a work of art like the 'Cualnge Cattle-Raid,' but it is not a finished epic, but an epic in the making, showing better perhaps than any other work in literature the development of popular tradition through more than a thousand years and the earlier stages of an epic. It affords a picture of "an old barbaric civilization," with
all its inherent imperfections and roughness, wild phantasy and extravagance of deed and description, as it arose and developed among the people, was given form by poetic art. Withal it evokes poetic worth and contains some passages which are not surpassed in any literature.

The ‘Tân Bò Cualnge’ is a great tale, one of the greatest and most curious in the world, and of the utmost importance to the philologist, the folklorist, the archaeologist and the historian. For the first time in Europe it brings to light a high and romantic chivalry. It is a tale that is worthy of any literature in the world and no other race with which the Celts may be compared is able to produce any such ancient indigenous literary monument.

**Bibliography.**—The text of the Tâin, from the most important manuscripts, has been published by Ernst Windisch, ‘Die Altirische Heldensage, Tâin Ferta Cualng,’ Irische Texte, Etschband (Leipzig 1905), which contains complete apparatus, introduction, notes and vocabulary; Faraday, L. W., ‘The ‘Cattle-Raid of Cualnge’ (London 1904) is a translation based on the only manuscript of the letter, E. Cuchulainn Saga (London 1808); contains a translation by Standish H. O’Grady; Hutton, M. A., ‘The Tâin, An Irish Epic Told in English Verse’ (Dublin 1907) is a paraphrase, as is Gregory, Lady A., ‘Cuchulain of Muirtheimne’ (London 1903); on ‘The Ancient Irish Epic Tale, Tân Bò Cualnge, The Cualnge Cattle-Raid’ (London 1914) is the first complete version in English and (pages xxxii—xxxvi) contains a full bibliography on the subject.

**Joseph Dunn,**
Professor of Celtic Languages and Literatures,
The Catholic University of America.

**TAINAN, tî-nân,** Formosa, Japan, a city situated on a small river near the southwest coast of the island. Until 1896 it was the capital of the island. A canal connects it with Formosa Channel. Under the Chinese and Japanese regimes it has had the status of a treaty port. There are a rice mill and several sugar mills. Pop. 53,790.

**Taine, tan,** Hippolyte Adolphe, French critic and historian; b. Vouziers, Ardennes, 21 April 1802; d. Paris, 5 March 1893. He was educated at the Collège Bourbon and the Ecole Normale, Paris, was assigned by the government, which thought his talent dangerous, to a provincial post as instructor, but resigned this and devoted himself to literature, writing in quick succession ‘Essai sur La Fontaine’ (1853; rev. ed. 1860), ‘Essai sur Tite Live’ (1854) and ‘Philosophes Français du XIXe Siècle’ (1856). In 1864 he was appointed to a professorship in the Ecole des Beaux-Arts, where his series of lectures on the history of art were patterns of philosophical criticism. The dissolution of the empire and the attendant troubles directed him to the study of the philosophy of history and in connection therewith he wrote his ‘Origine des Lumières’ (Ancien Régime), 1876, ‘Revolution,’ 1878-84, ‘Régime Moderne,’ 1890—unfinished, a work of great erudition, in which he condemns the royalists, but finds their gravest faults repeated by the republicans, which makes his bitterest attack on Napoleon. Thus he alienated all parties, holding all responsible for the disasters of the ‘Terrible Year.’ A work more far to readers in the United States and England, by Van Lennep, ‘Histoire de la littérature anglaise’ (Englische Texte, Etschband (Leipzig 1905), which contains complete apparatus, introduction, notes and vocabulary; Faraday, L. W., ‘The ‘Cattle-Raid of Cualnge’ (London 1904) is a translation based on the only manuscript of the letter, E. Cuchulainn Saga (London 1808); contains a translation by Standish H. O’Grady; Hutton, M. A., ‘The Tâin, An Irish Epic Told in English Verse’ (Dublin 1907) is a paraphrase, as is Gregory, Lady A., ‘Cuchulain of Muirtheimne’ (London 1903); on ‘The Ancient Irish Epic Tale, Tân Bò Cualnge, The Cualnge Cattle-Raid’ (London 1914) is the first complete version in English and (pages xxxii—xxxvi) contains a full bibliography on the subject.

TAINANT, Charles Sumner, American inventor; b. Watertown, Mass., 25 April 1816; d. Boston, 14 February 1890. He invented the graphophone and was associate inventor of the radiophone. In 1881 he was made a member of the United States delegation sent to the South Pacific to o the transit of Venus. In 1881 he received a gold medal at the Electrical Exhibition, for his inventions in connection with the telephone and in 1889 was given the French emy decoration, ‘Officier de l’Instruction Lique’ for the invention of the graphophone in 1890. He received the John Scott Medal of the Franklin Institute for this same invention of the graphophone in 1890.

Tait, Peter Guthrie, Scottish physicist: b. Dalkeith, 28 April 1831; d. Edinburgh, 25 July 1901. He was educated at the Edinburgh Uni-
versity and at Saint Peter's College, Cambridge. Elected Fellow of Peterhouse in 1852, he be-
came professor of mathematics at Queen's Col-
lege, Belfast, two years later, and held that
office till his appointment in 1860 to the chair
of natural philosophy in the University of
Edinburgh. He published 'Dynamics of a
Particle' (1856); 'Quaternions' (1867);
'Thermo-Dynamics' (1868); 'Recent Advances
in Physical Science' (1876); 'Heat' (1884);
'Light' (1884); 'Properties of Matter' (1885);
'Dynamics' (1895); 'Newton's Laws of Mo-
tion' (1899), etc. He was joint-author with
Lord Kelvin of a well-known 'Treatise on
Natural Philosophy', and also collaborated
with the late Balfour Stewart in 'The Unseen
Universe'.

Taito, ti-wan', the native name for
Formosa (q.v.).

Taj Mahal, tāzh, ma-hāl', India, a cele-
brated mausoleum in a beautiful garden, out-
side the city of Agra, about a mile east of
the fort. It was built by the Emperor Shah Jahan
for himself and his favorite wife Mumtaz
Mahal, who died in 1629. Tavermier, who saw
the building in process of construction, says
that 20,000 men were employed upon it con-
tually for 22 years. It is an octagonal building
70 feet high, with sides measuring 130 feet,
and is surmounted by a dome giving an addi-
tional height of 120 feet; total height, 190 feet.
At the four corners of the platform centred by
the mausoleum are minarets 133 feet high. The
whole is built of white marble, and the interior
decorations are of sumptuous magnificence.
The screen surrounding the chamber contain-
ing the cenotaphs of the emperor and his con-
sort, above the sepulchral vault, is composed of
12 kinds of stones, chief of which is the
valuable lapis lazuli; the arabesque mosaic and
inlaid work is described as of unsurpassed
beauty. The cost of the mausoleum is vari-
ously estimated to have been from $10,000,000
to $50,000,000.

Tajura, or Ta'jurah, tā-joorā, northeas-
Africa, a bay and seaport in the
French Somali Coast protectorate or territory
of Obock, on the Gulf of Aden. It was ceded
to France in 1884. The rising French seaport
of Jibuti is at the entrance of the bay, on the
south side, whose a railway extends since 1902
to Harar. See Asvrasint.

Tak-i-Kesra. See Ctesiphon.

Takahashi, tā'-ka-hā-shē, Korekiyo,
Ban fills, Japanese financier: b. Sendai, 7 July
1854. He studied English in Japan, then, for
one year, in America. In 1875 he was ap-
pointed principal of the Osaka English School,
becoming (1881) official in the Department of
Agriculture and Commerce. In 1892 he en-
tered service of the Bank of Japan, becoming
the following year director of its western sec-

in 1895 he entered the Yokohama Specie
Bank as manager, becoming, successively, di-
ector (1896), vice-president (1897), and was
then appointed vice-governor of the Bank of
Japan, returning (1906) to the Yokohama
Specie Bank as president while retaining his former position. From 1904-06 he negotiated important loans from England and America. He was created baron in 1907.

TAKAHIRA, taka-hēra, Kogoro, Baron, Japanese diplomat; b. Iwate, 1854. He was appointed attached to the legation at Washington in 1879 and became secretary in 1881. Later he was made chargé-d'affaires at Korea, then consul-general at Shanghai and (1887) New York, following which he was successively appointed Minister-Resident to Holland and Denmark, Minister-Plenipotentiary at Vienna, Vienna and Berne. From 1901-05 he was minister at Washington, in the latter year signing, with Baron Komura, the Peace Treaty at Portsmouth, N. H. He was Ambassador at Rome (1907), then transferred to Washington the following year, serving till 1909.

TAKAMINE, taka-miń, Jokichi, Japanese-American chemist; b. Takaoka, Japan, 3 Nov. 1854. He was graduated in chemical engineering (1879) at the Engineering College of the Imperial University at Tokyo, becoming Japanese government student at the Glasgow University and Andersonson University, Glasgow, from 1879-81. From 1881-84 he was head chemist of the Department of Agriculture and Commerce, Tokyo; then (1884-85) Imperial Japanese Commissioner to the Cotton Centennial, New Orleans. In 1887 he organized and erected the first super-phosphate works at Tokio. He came to America in 1890 where he brought to the attention of the public the process to practical use producing diastatic enzyme, now used in starch factories. He established a research factory in New York, and with others, formulated a process of extraction of the active principle of the suprarenal glands on a commercial scale, producing 'adrenalin.'

TAKAMATSU, taka-māt-soo, Japan, the capital of the prefecture of Kagawa, situated on the north coast of Shikoku. Pop. 40,000.

TAKAOKA, taka-ōka, Japan, a town in the prefecture of Toyama near the west coast of central Honjo. It manufactures dyes and hardware. Pop. about 40,000.

TAKASAKI, taka-sā-ke, Japan, a town in the prefecture of Gunma, situated nearly in the centre of Honjo, 60 miles northwest of Tokio, with which it has railroad connection. It has cotton and silk manufactures. Pop. 34,900.

TAKATA, taka-ta, Japan, a town in the prefecture of Niigata, near the west coast of central Honjo. It has extensive manufactures of cotton goods. Pop. 32,600.

TAKIGRAPHY. See SHORTHAND.

TAKILMAN FAMILY, a tribe of American Indians occupying the country along the Rogue River in Oregon. In 1860 there were some 17 villages of this tribe but it is now scattered or extinct.

TAKOW, tā-kow', or TA-KAO, tā-ō-o', Formosa, a port on the southwest coast, connected by rail with Taihain. Its principal export is sugar. Pop. 15,000.

TAKU, a tribe of North American Indians, residing in the vicinity of Taku Inlet, Alaska. They number about 300.

TALACOGAN, tā-lā-kō-gān, Philippines, a settlement of Moros, province of Surigao, Mindanao, on the Agusan River, seven miles of the outlet of Lake Pinatay, and 96 miles of Surigao, the provincial capital. Pop. 16,500.

TALAMANCAS, tā-lā-mān-kā, Pana name formerly applied to the Atlantic region of western Panama and Costa Rica. At the time of the Discovery the region was inhabited by numerous tribes with a partially civilized form of their own. They manufactured a great variety of ornaments of gold, and the accounts of the explorers concerning the friendship and hospitality of the whites they were driven in forest and mountain recesses. Here a known as Talamancans still lives in primitive independence and wholly unaffected by civilization within a short distance of Panama Railroad.

TALAVACHI, a mysterious poison manufactured by the Aztecs, and by handed down to the Mexican Indians. Fully administered, it is said to destroy mind while leaving slight effects on the body. The peculiar effect of the poison seems to induce monomania or epilepsy.

TALBOT, Arthur Newell, American geologist; b. Cortland, Ill., 21 Oct. 1857. He graduated (1881) at the University of Illinois, receiving his civil engineer's diploma in geology. He has been engaged in engineering work on railroads, sewerage, waterworks and other public utilities as well as in the investigation and construction of materials. Since 1890 he has been professor of civil engineering at the University of Illinois. He was elected president of the American Society of Civil Engineers. He has written "The Railway Transition Spiral" (1893); "Tests of Concrete" (1901); "Tests of Concretes" (1912); "Tests of Reinforced Concrete" (1913).

TALBOT, Ethelbert, American Protestant Episcopal bishop; b. Fayette, Mo., 9 Oct. 1816. He graduated from Dartmouth College in 1870, and from the General Theological Seminary in 1873. He was ordained in the Episcopal church in the year last named and was rector of Saint James, Macon, Mo., 1863-87. In 1873 he was consecrated missionary bishop of Washington and Idaho, and in 1879 was translated see of Central Pennsylvania. After admiring the diocese of central Pennsylvania for seven years he accomplished his division in the diocese of Bethlehem of which he was bishop with residence at South Bethlehem and the diocese of Harrisburg. He is the author of "My People of the Plains," "Bishop Among His Flock," and "Tim: a Tabor of a Dog." Besides these he has published various sermons, addenda, and tracts.

TALBOT, Henry Paul, American chemist; b. Boston, 15 May 1854. He was graduated (1885) at the Massachusetts Institute of Technology and obtained Ph.D. diploma at L. in 1890. He has served successively as assistant (1885-87), instructor (1887-88 and 1892-93), associate professor (1893-95), and professor of chemistry (1896-1902) at the Massachusetts Institute of Technology, where he has since charge of the department of chemical engineering. He has written...
y Course of Quantitative Chemical (1817); 'The Electrolytic Dictionary,' in collaboration with A. A. d (1905); besides numerous articles in the scientific journals.

**BOT, John, 1st Earl of Shrews:** about 1380; d. Castillon, France, 173. He was appointed lord-lieutenant of France by Henry V in 1414. Five years began a long career in the French wars, at the siege of Milan in 1420, and Meaux in 1421. He returned to Ireland-lieutenant in 1424 and was knighted out in 1427' went again to France. After the siege of Orleans he determined the town of Beaugency; but the place had already been evacuated, and northward toward Patay, where for the French and captured. He regained his freedom by exchange. In 1436 he became a marshal of France, 1439 had become governor and lieu-tenant of France and Normandy. The of Harfleur in 1440 was largely due to 1445 he conducted Queen Margaret to and that year went for the third time d, where to his titles were added those of Waterford and Lord of Dungarvan. He crossed the channel again as lieu-tenant of Normandy. In 1453 he went to the siege of Castillon, and against great odds until he was killed.

**BOT, John, American Protestant missionary:** b. Wymondham, Norfolk, 1645; d. Burlington, N. J., 29 July. He entered Christ's College, Cambridge in 1664, f Freethinker, Gloucestershire, in 1695, red the employ of the English Society Propagation of the Gospel in Foreign Parts. He came to America, founded the Church, Burlington, N. J., and rector 1704-22. His later loyalty to the Church appears to have fallen into for the two sides of the controversy. His 'History of the Church in Bermuda (1876),' and Perry, 'History of the Episcopal Church' (1885).

**BOT, Silas, American naval officer:** on, Bristol County, Mass., 1751; d. New June 1813. Upon the breaking out of the War he was commissioned in a Rhode Island regiment, and after the siege of Boston, accom-panied the army in 1776 to New York. For the which he directed certain operations the British shipping in the harbor he from Congress a major's commission. He participated in the memorable defense of Boston, November 1777, and in 1778 ren-ovable assistance to General Sullivan by tiring the American forces from the to the upper end of the island of Savannah. He was promoted to the rank of major in 1778 of the British floating Pigeon of 22 guns, anchored in one of the necks commanding the approach to New- n 1779 he was commissioned captain, and was assigned to a vessel with success British commerce, was captured by a fleet and confined in the Jersey prison. He was afterward removed to England, and in 1781 was exchanged. Upon the reorganization of the navy in 1794, he was again called into the public service, and superintended the construction of the frigate Constitution (Old Ironsides), which in 1799 was her flagship during a cruise in the West Indies. He resigned his commission in 1801, and passed the remainder of his life in New York. Consult Tuckerman, 'Life of Commodore Silas Talbot' (1851).

**TALBOT, William Henry Fox,** English photographer and scientist: b. Lacock Abbey, near Chippenham, England, 11 Feb. 1800; d. there, 17 Sept. 1877. He was graduated at Cambridge in 1821, and represented Chippenham in Parliament 1833-34. Scientific research being more attractive to him he gave up politics, and, devoting himself to the study of the chemical action of light, made important discoveries in photography. In 1839 his invention of pho-togetic drawing was explained by Faraday to the Royal Institution, and in 1841 he patented the calotype process. He is still referred to as an authority whose statements are sound. Subsequently Talbot devoted himself to antiquarian research, being one of the first decipherers of the cuneiform inscriptions from Nineveh. His publications include 'Chemical Changes of Color' (Phil. Magazine 1828); 'Legendary Tales' (1830); 'Hermes, or Classical and Antiquarian Researches' (1838-39); 'The Pencil of Nature' (6 vols. on photography 1844-46); ' Assyrian Texts Translated' (1856), etc.

**TALBOT, or OLD SOUTHERN HOUND,** a race of dogs, probably extinct, which seems to have been the original stock from which the various breeds of hounds sprang. The color was pure white; large head, very broad muzzle, long pendulous ears and rough hair on the belly. Talbot is the family name of the English house of Shrewsbury which has a talbot for badge and two talbots for supporters.

**TALC,** one of the commonest and most important of the non-metallic minerals. It is usually massive or foliated, the laminae being flexible but not elastic. It is number one in Mohs scale of hardness, and like most very soft minerals it has a greasy feel. It is pearly and glimmering, and its usual colors are green, gray or white. Foliated varieties are often quite transparent, while the massive is translucent. It is of average specific gravity, about 2.7. It is acid magnesium silicate, \(\text{H}_2\text{MgSiO}_3\). Talc, like the related mineral serpentine, is of secondary origin, having been formed by the alteration of various magnesian minerals such as tremolite, pyroxene and enstatite. It occurs in metamorphic rocks all over the world, being the most prominent mineral in the rock known as talcose schist, and sometimes forms extensive beds, occurring thus in most of the Atlantic Coast states. Although very soft, it is almost indestructible, not being attacked by acids nor injuriously affected by water. Its common, massive form, popularly known as "soapstone," is the "estatite" of mineralogy. Some soapstone is, however, a massive pyrophyllite (q.v.) and the term soapstone is applied loosely by miners to almost any soft rock or mineral with a greasy feel. Talc is used in the arts either powdered as "flour talc," or in sawed pieces. Flour talc is employed as a base...
for fireproof paints, in boiler and steampipe coverings, and foundry facings, for electric insulators, in the manufacture of dynamite, and of wall papers to which it imparts a glossy surface; it is very extensively used in the manufacture of toilet powders, and cheap soaps, for dressing leathers and skins, and as a base for lubricants. About half a million dollars' worth of "fibrous tale" is produced annually in the single county of Saint Lawrence in New York. This material is a mixture of tale and fibrous tremolite and is used in making paper. When ground the fibres cause the retention of the flour tale in the paper pulp, thus adding materially to the strength and weight of the paper.

The supply of pure, compact soapstone, the most valuable variety of tale, comes largely from western North Carolina and Virginia. It is sawed into slate pencils and crayons and is manufactured into the tips of gas burners. The chief uses of soapstone are for stationary wash-tubs, sinks, acid tanks, hearth-stones, fire bricks, newel posts and many other articles of everyday use. "French chalk" is a fine-granular tale used as a crayon by tailors. In China and Japan a fine compact tale is carved into various ornaments, household gods and pagodas, though the material thus used is azagatalite (quartz) or pyrophyllite. See MINERAL PRODUCTION OF THE UNITED STATES.

TALCA, tāll'kā, Chile, the capital of the province of the same name, on the Rio Claro, about 180 miles south of Valparaiso, on the railway from Curico to Concepcion. It is a fine city with handsome churches and a lycceum. Weaving is the chief manufacturing industry. Pop. (1913) 41,618. The province has an area of 3,964 square miles and the population is 131,058.

TALCAHUANO, tāl-kā-wā'no, Chile, a seaport in the province of Concepcion, situated 200 miles south of Valparaiso, and eight miles west of the city of Concepcion, with which it has railroad connection. It has a lighthouse, a new custom-house, a wireless station, and large warehouses and docks. The harbor is being fortified. It is the principal export town for wool in Chile. It was severely from earthquake in 1835, but was rebuilt. Pop. 21,876.

TALE OF A TUB, A, and THE BATTLE OF THE BOOKS. Swift's "A Tale of a Tub" was written for the most part about 1696, but was not published till 1704, when it appeared as a volume with "The Battle of the Books." The author wittily dedicated it to Prince Posterity, and to this day it has generally been regarded as one of the two or three great prose satires in English. Not the least interesting parts of it are the diverting chapters on critics and criticism and on madness, in which the theory is advanced that happiness consists in being well deceived. Its most fruitful fancy is of the sect who took the tailor for their exemplar, and to him it was to be a large suit of clothes — the term of Carlyle's "Sartor Resartus." The allegorical narrative presents the fortunes of three brothers, Peter, Martin and Jack, standing respectively for the Roman, the Anglican and the Nonconformist. Their father on his death-bed bequeathes them each a coat with two virtues: "One is, that with good bearing they will last you as long as you live. The other is, that they will grow same proportion with your bodies." The time the boys wear their coats in age with their father's will. Later they go to town and fall in love with the three most in reputation, the Duchess d'Orgueil and Madame de la Salle, and the Vicomte and Marquis de la Homemade. Desiring to be in the field, they violate their father's will, covering with shoulder-knots, silver fringe and embroidery. Peter becomes dictatorial. Jack resists being addressed by his brother Peter, Father Peter and finally as Peter. Martin and Jack revolt from authority, and, in token of repentance, at remove the embellishments from the in which process Martin, reforming, restores his garment to its original state, but Jack in a fury rends his from top to bottom. It is asserted that he had written as a good man, ridiculing only Popery and Diaseitts were delerious. Anglicans were alarmed at its implication; it is undeniable that its disgusting and brutal levity was inimical to the cause of religious reverence. The satire was explained by William Wotton; but explanations were maliciously seized upon to make it serve as annotations in subsequent editions. As an old man Swift is said to have exclaimed: "Good God, what a genius when I wrote that book!"

"The Battle of the Books," written 1697, was Swift's contribution to the literary controversy of the 17th century, regarding the relative merits of ancient and modern writers. In England the di menace was rendered rather insignificant by the confusion of the champions, the wits appearing as defenders of the ancients, the great classical scholar of the leader of the moderns. The conflict was settled by the "Letters of Phalaris," which William Temple, in his "Essay Upon the Ancient and Modern Learning" (1692), declared the more of grace, more spirit, more force and genius than any others I have seen since ancient or modern. Leibnitz, "Letters of Phalaris," said Temple, is one of the finest ancient books in prose that we possess. Temple, championing the moderns in 1694 with "Reflections Upon Ancien" and "Modern Learning." In 1695 Charles brought out an edition of the extolled in behalf of the ancients. In 1697 Wotton published a second edition of the "Reflection", including an essay by the learned Richar ley, showing that the "Letters of Phalaris" were forgeries and, relatively, much about this point Swift comes in with book of the Books," written for the the ancients and in support of his Temple, the immediate object being to laughter of the town upon Wotton as a fellow. Swift was on the wrong side with the Phalaris question and with re the scholarship of the enemy. But he a flight of nicely pointed arrows at the politer and kinder criticism and vanity of the moderns, and the course of the dispute between the the Bec he strikes out an idea and with which Matthew Arnold adopted and pop

STUART P. SHERMAN,
Professor of English, University of Illinois.

TALE OF TWO CITIES, A, published in 1859, was the second of Dickens' historical novels and is to-day more popular than the author's earlier novel of the same kind, 'Barnaby Rudge' (1841). The reason lies partly in the fact that the French Revolution is a more permanently interesting historical event than the anti-Catholic agitation and the Gordon riots in London. The chief purpose of the novel is to give an impression,—in this case a very English impression with its roots in the anti-Napoleonic tradition,—of the days of the old Régime and the French Revolution, in which cynicism, arrogance and cruelty, on the one hand, and guillotining, on the other, were the prominent features. No account is suggested of the intellectual causes of the Revolution. It is a picture of action. The turbulence of Paris compared with the dignified and law-abiding ways of London give the book its title.

The story is the account of the escape from France of the emigré, Saint Evremonde, or Charles Darnay, of his return to France, his arrest, condemnation through the unwitting evidence of his own father-in-law, and his final escape through the self-sacrifice of Sidney Carton. This last is the most famous part of the book, both ethically and episodically. Sidney Carton, the real hero, takes advantage of his resemblance to Charles Darnay to mount the scaffold in place of the latter, who is meanwhile hurrying disguised to England with his family. The story is a moving one and is almost wholly lacking in the usual humorous scenes and characters of the author. It has been successfully dramatized. Certain of the scenes, notably the flight from Paris, the death of Carton, and the women knitting differentiately at the executions, have become famous.

WILLIAM T. BREWSTER.

TALENT, the name of a weight and denomination of money among the ancient Greeks, and also applied by Greek writers to various standard weights and denominations of money of different nations; the weight and value differing in the various nations and at various times. The Attic talent as a weight contained 60 Attic mina or 6,000 Attic drachmae, equal to 36 pounds, 11 ounces, British Troy weight. As a denomination of silver money it was equal to $1,220. The great talent of the Romans is computed to be equal to $500, and the little talent to $375. A Jewish weight and denomination of money, equivalent to 3,000 shekels, also receives this name. As a weight it was equal to about 93¾ pounds avoirdupois; as a denomination of silver it has been variously estimated at $1,500 to $1,880.

TALES OF THE ARGONAUTS, The. The Tales of the Argonauts is a volume of short sketches collected and published by [Francis] Bret Harte in 1875; but the title is sometimes loosely applied to all this author's stories of early California. Nothing in the 'Tales of the Argonauts' proper quite equals in merit 'The Luck of Roaring Camp,' 'The Outcasts of Poker Flat' and 'Tennessee's Partner,' which had appeared in an earlier collection; but 'An Iliad of Sandy Bar,' 'How Santa Claus Came to Simple Simon's Bar,' and 'Harte's' Argonauts have been deservedly popular. The Argonauts are of course the gold-seekers of 1849 and the years immediately following. These adventurers came from all quarters of the globe and all ranks of society, and they had in common only the possession of the strength and determination necessary to reach the new Colchis. Here they lived, at first, wholly free from the conventional restraints imposed by an organized society, and each man showed himself for what he was. Many of these primitive social conditions still existed when Harte went to California in 1854, and they made a great impression on the observant boy. He did not use them in literature, however, until he was able to look back on them in his experience. Californians objected that his pictures were unreal; but they give the impression of essential truth to life—a more serious work not spoiled by his persistent habit of showing the good elements in even the lowest and most debased characters. Harte occasionally seems to have adopted some of the less fortunate devices of Dickens, but his manner was chiefly his own. He lacks literary finish, though he was painstaking in regard to style; but in these early tales he has a sure command of humor and pathos, and a complete mastery of his unique material.

WILLIAM B. CAIRNS.

TALES OF THE CRUSADERS, two novels by Sir Walter Scott, respectively entitled 'The Talisman' and 'The Betrothed.'

TALES OF A GRANDFATHER, a collection of stories dealing with the history of Scotland, by Sir Walter Scott, and published in four series in 1827–30.

TALES OF HOFFMAN (Les Contes d'Hoffmann), Opera comique in prologue and three acts by Jacques Offenbach (libretto by Eugène Scribe and Barbier), first produced at L'Avenue in Paris, in several months after the composer's death. In spite of the unparalleled success which Offenbach had achieved with his light-hearted, clever and unfailingly melodious *opéras bouffes*, he evidently desired to bequeath to posterity a work of more serious artistic import; and he spent his most ambitious efforts and years of his life on the 'Tales of Hoffman.' As his end approached, he begged the manager to produce it in time for him to witness the première. While he did not live to see it, the public took to the work no less heartily than to the operettas and it will undoubtedly outlive them. The story is novel and cleverly put together. The prologue shows Hoffman and his fellow students in Luther's Inn at Nuremberg, and proceeds to tell of his three love encounters and these form the three succeeding acts. The opera ends as it began, Hoffman acclaimed a hero by his admiring friends. Inspired by its romance and fantasy, Offenbach has written a genuine and attractive score, which displays his talent for melody-making and ingenious characterization at its best. The barcarolle, in the second act, once heard, is never to be forgotten. Alone it
TALES OF MY LANDLORD—TALIAFERRO

would have made the opera, but there are many other numbers worthy of recall—
the burlesque ballad of Kleinzach, sung by Hoffman in the prologue and epilogue, Nicklausse's song of the doll, the automaton's song, *Les oiseaux dans la chance* and Antonio's romance, *Elle a su,* and the trio finale of the third act. Offenbach's treatment of the dramatic situations is always clever and at times subtle. The orchestration, while simple, is refined and the general effect is a great deal above that on which he was usually content to stand. In Europe, *Tales of Hoffman* has been pursued by superstitious fear on the part of the managers owing to the fact that its first performance at the King Theatre in Vienna was the occasion of a conflagration which caused great loss of life. Its revival in New York by Oscar Hammerstein in 1907 proved that its original appeal is still potent.

LEWIS M. ISAACS.

TALES OF MY LANDLORD, a name applied to four series of Scott's novels, the first embracing 'Old Mortality' and 'The Black Dwarf'; the second, 'The Heart of Midlothian'; the third, 'The Bride of Lammermoor,' and 'A Legend of Montrose'; and the fourth, 'Count Robert of Paris,' and 'Castle Dangerous.'

TALES OF A TRAVELLER, a well-known work by Washington Irving, published in 1824. It is a delightful medley of humorous and tragic elements and the author himself declares to be "moral tales," with the moral disguised as much as possible by sweets and spices.

TALES OF A WAYSIDE INN. The 'Tales of a Wayside Inn,' by Henry Wadsworth Longfellow, was published in three parts, in 1863, 1872 and 1873, respectively. The poet followed the old plan of presenting a series of stories as told by different persons—in this case by friends of the author who, though they were not named, were so plainly characterized as to be easily recognizable. Among those of wider fame are Ole Bull, the violinist, and Thomas William Parsons, the poet. The inn is the "Wayside Inn" Old Red Horse Inn at Sudbury, 20 miles from Cambridge—a favorite resort for parties from Harvard College. Each of the three parts has a prelude and a finale, and there are interludes which link together the tales and introduce the narrators. Most of the stories were derived by Longfellow from his wide reading—many of them from the legends of continental Europe, a few from American sources. The 'Birds of Killingworth' was developed from a slight hint that it may fairly be said to be of the poet's own invention. Longfellow, while not a poor story-teller, was hardly at his best in narrative, particularly in narrative with vigorous action, and the 'Tales of a Wayside Inn,' taken as a whole, is not to be listed among his most distinguished works. A few of the Tales have, however, won a place for themselves. Among these are 'Paul Revere's Ride,' told by the landlord, and 'King Robert of Sicily,' which is ascribed to the Sicilian.

WILLIAM B. CAHNS.

TALESMAN. From the Latin *talis*, such, or of such a kind and quality. A talesman is a juror summoned to fill up a panel for the trial of a particular case. A default appears to have but one immediate result, common law, that is to select *tales de standibus* (those by-holders who are tent) in sufficient number. A number of statutes forbid summoning standers but the procedure is main, in most jurisdictions, and the method is legal unless forbidden by statute. It appears to be no set limit to the number of the emergency roster on which one could be drawn or of the panel being exhausted and delirious jurors existing. Talesmen can only be called for a single trial, not for a Talesmen are considered strictly as jurors, not called to form a new panel. In some States it has been held that one may be made up entirely of talesmen all the panel has been discharged or to some other case or when a "challenger array" has been sustained, but such action has been denied and the usual employed is to issue a new venire.

TALFOURD, täl'verd, Sir Tho. The English poet: b. Reading, 26 May 1770, Ford, 13 March 1854. He was called to the bar in 1821, but was early called to bar by literary labors as a contri- various periodicals. In 1835 and 1837 he returned to Parliament as one of the peers for Reading; and between these years his Covent Garden his tragedy of 130 tragedies subsequently written by him are 'The Athenian Captive'; 'Glencoe, or of the MacDonalds'; and the 'Cabinet' of these had the same success as the drama of his excellence lies more in the language and sentiment than in the dramatic action. In 1849 he was raised to the Court of Common Pleas. He died suddenly while on grand jury. Besides the dramas above to, he was the author of 'Life of Lamb' (1837); and the same in a larger edition (1848).

TALIAFERRO, töl'é-ver, William American soldier and lawyer: b. B Gloucester County, Va., 26 Dec. 1822; and at William and Mary College, baniested from the latter in 1841. He studied law, and was engaged in the practice profession until 1847, when he became in the United States infantry, later promoted major, and in August 1848 entered out and resumed his law practice. In the outbreak of the Civil War he beca in the provisional army of Virginia, he was promoted brigadier-general in the federal army and in 1865 major-general commanded at Gloucester Point, Va., in most of the battles of the Army of Virginia until March 1863, when he was in charge of the district of Savannah, July 1863 he was in command of the defense and defenses on Morris Island, at the charge of Fort Wagner (q.v.) against a combined land and naval attack. Later command of the district of South Carolina. He was elected to Congress at the lature and served 10 years during the construction period. He was prominent in Masonic fraternity and was Master of the Masons of Virginia in 1876-77.

SMAN, a small object presumed to

astrological or mystical charm that

may protect or guard the owner in some way.

It was usually of stone or metal and bore an

carved figure, and gained its suggested value

because of certain ceremonies, at some particu-

lar moment, as at the culmination of a certain

star or at the conjunction of certain planets.

The talisman was supposed to exercise super-

natural influences over the bearer or owner,

particularly in averting disease. The nature of

the talisman has been very different among dif-

ferent nations. The Egyptians made use of

images of their gods and of sacred animals,

such as the ibis and the scarabaeus; the Persians

used the phylacteries inscribed with passages

from the Old Testament (a section of the cabala

is devoted to teaching the construction of talis-

mans); the Greeks used little tablets having

written upon them various magical words, such

as the Ephesian words, or those written on

the feet, the girdle and the crown of the statue

of Artemis at Ephesus; the Romans employed

various idols, which they suspended upon

the body by chains; the Arabs and Turks made

use of sentences from the Koran; and we also

find in the East medals of particular metals

struck under a particular constellation and

marked with magical signs. In the Middle

Ages astrology and the knowledge of the

tances of talismans and amulets formed an im-

portant part of medical science; and the quacks

of modern times sometimes have recourse to

similar means. The talisman differs from the

amulet, in that it does not require to be worn

or carried, but like Aladdin's lamp will work

wonders. See FETISH.

TALKING MACHINE. The wonderful,

though natural, growth in popularity of the

talking machine has caused its manufacture

and sale in the few years that have passed since

its perfection to become a truly great industry.

Its utility for entertainment purposes in the

home no doubt aids in the absorption of most

of the instruments constructed in the compet-

ing factories, but the use of talking machines

in commercial life (dictaphone perhaps in par-

icular), greatly aids the numerical demand and

it is found a valuable aid in teaching foreign

languages. History mentions talking machines

as early as the 13th century, when Albertus

Magnus, the philosopher and scholar, is said

to have produced a mechanism that reproduced

the human voice. A queen of Sweden is said

to have had a head which talked automatically

in Hebrew, Greek, Latin and French. The

Reverend John Wesley writes in his journal at

date 26 April 1762, that he saw an invention at

Lurgan, Ireland, of startling capabilities. It

was "an automaton of an old man in a case

over against a clock . . . Every time the

clock struck he opened the door with one hand,

drew back the curtain with the other, turned

his head, but then said with a clear, loud

articulate voice, 'Past one, two, three' and so

on." The invention was contrived by a man

named Miller. But so many visitors called

from foreign parts to see this wonder, and no

one offered to purchase it, that it took up his

time so much he nearly failed in business; he

"took the whole machine to pieces." This

Miller told the preacher later he had made

very successful experiments and could make a

man who could talk and sing hymns, but he

was too busy on other work. In 1783, Abbe

Mical presented to the French Academy of
Sciences an invention that talked, but he later broke it up, having religious scruples.

In 1877 Thomas Alva Edison brought out his first talking machine. The contrivance was of the simplest, being merely a steel point fixed to the centre of a flexible disk and a revolving cylinder behind the point. It was first displayed in Paris. The invention was enclosed in a little box about a foot square and the record was made on a piece of tin-foil. As a woman's voice was first used, it created great admiration. In 1888 Edison constructed his phonograph with its diaphragm having the lateral movement instead of the cylinder and the sheet of tin-foil was discarded in favor of a cylinder of wax, the vibrations being recorded with a tiny chisel. Edison is said to have gained his incipient conception of a talking machine while working with automatic telegraphs operating at high speeds. He made some experiments with embossed strips impressed with dashes and dots thereon which were moved rapidly beneath a stylus to vibrate it. He observed the stylus made audible sounds while vibrating, and as the great inventor never passed by mechanical facts, however trivial, that did not appear to the ordinary investigator, he became interested in this curious sound phenomenon. He was about this time working on telephone experiments and the idea of a new sound developer occurred to him as a possibility. The conception of developing a talking machine soon grew in his mind and under his expert hands he soon had his first talking machine—getting his first patent 19 Feb. 1878, No. 200,521, with its tin-foil records.

The graphophone was an outcome of much experimentation by laboratory experts and at its inception the sewing machine was becoming a highly popular home machine. Therefore the manufacturers at first used the sewing-machine stand (frame, treadle and table top) in their first output, as motive power which was manufactured in the East Bridgeport vacated building of the Home Sewing Machine Company. It met with poor success and the spring motor was invented which made it portable and sales grew rapidly. Next the cylinder form of record was developed and then the flat record. The listener had been using a number of tubes for the ears: these gave way to the horn for the dissemination of the sound leaving the ears naked and the sound audible at a distance. Later again the unguarded horn and all the mechanism was enclosed in a box or a cabinet.

Emil Berliner invented the gramophone apparatus in 1892 with a smoked disc and stylus to produce sound vibrations. See GRAMOPHON, GRAPHOPHONE, PHONOGRAPHER, etc.

**TALL FESCUE.** See GRASSES IN THE UNITED STATES.

**TALL OAT-GRASS.** See GRASSES IN THE UNITED STATES.

**TALLADEGA, Tal-ä-de'ga.** Ala. city, county-seat of Talladega County, on the Southern, the Birmingham and Alabama, the Louisville and Nashville and Atlanta, Birmingham and Atlantic railroads, about 70 miles east of Birmingham and 100 miles north of Montgomery. The city is in a fertile agricultural region, in which there is also considerable mining. The chief industrial establishments are three cotton factories, two machine shops and grist mills, the $200,000 chemical plant, cottonseed-oil mill, three lumber and planing mills. There is considerable trade in grain and cotton. The educational institutions are the Synodical Female College, Alabama Academy for the Blind, Alabama School for the Deaf-Mutes, Alabama Institution for Deaf, Dumb and Blind, and Talladega College (colored), opened in 1869, under the auspices of the Congregational Church, and public schools. There are several churches and one orphanage. The two national banks have a combined capital of $150,000. State bank $50,000, deposits over $1,000,000. Pop. about 5,854.

**TALLADEGA, Battle of, in the War of 1812.** On 7 Nov. 1813, four days after the battle at Tallushatchee Jackson learned that 160 friendly Creek Indians in Lashly's Fort at Talladega, about 30 miles south of Fort Strother, were besieging some hostile warriors and were in danger of capture. Accordingly, with 1,200 infantry and 800 cavalry, he set out and on the 9th had approached within 80 yards of the Indians before he was discovered. Jackson arranged his plan of battle so that the Indians would be surrounded, but in the fight three companies of militia gave way and allowed many Indians to escape. Jackson's victory was decisive, 290 of the enemy being found dead on the field while his own loss was 15 killed and 85 wounded. Jackson returned to Fort Strother 10 November where he was forced to remain idle until the battle of Emuckfaw (q.v.). Consult Brackenridge, H. M., 'History of the Late War,' pp. 190-191; Lossing, 'War of 1812,' pp. 762-763; Wiley and Rines, 'The United States,' Vol. V, pp. 448-449; biographies of Jackson by Parson (Vol. I, pp. 440-444); Buell (Vol. I, pp. 305-310) and Frost (pp. 142-346).

**TALLADEGA COLLEGE,** located Talladega, Ala. It is open to all persons without regard to color or race, but is primarily for the education of colored students. The work is arranged to meet their needs. It was founded in 1867 by the American Missionary Association (Congregational), aided by Freedman's Bureau; and was the first open to colored pupils in Alabama; the university was obtained in 1869. A farm was bought in 1877, additions to it were made in 1887 and until the land owned by the college in about 800 acres. The college is coeducational and aims to secure the best development of social character by the association of students of both sexes under the same general discipline and careful supervision. The college organization includes seven departments. The educational department offers three courses, the classical course including the study of the Biblical languages, Hebrew and Greek, leading to the degree of B.D.; the English course, the same as the classical without the study of the Bible in the original languages; the Bible training course of two years, including the usual study of the Bible without the other studies of the usual theological course. The college department offers two courses, the classical and the scientific, leading to the degrees of A.B.
and the college preparatory depart-
ments two corresponding courses of three
years each in the high school for boys and
girls, beginning in the first year and
graduating in the third year. The col-
lege preparatory department is com-
posed of three years of college prepara-
tory work, the first year being used as
the first year of the college prepara-
tory course. It includes practice work in
the primary grades, and the intermediate
grades. The departments are organized
and taught in all grades, in addition to
which the college preparatory depart-
ments are in charge of the housekeeping
in the dormitory, the girls' industrial
house, and in the department of agriculture.
In the manual training department,
the girls are taught woodworking,
drafting, in the eighth grade in forge-
ing, in the ninth grade in sewing and
dressing, and in the tenth grade in cooking.
Instruction is given to students in the preparatory
courses of the college in agriculture and
manual training. The buildings are situated
on high ground a mile from the city; they include
the main college building, the hall (theological building),
Foster Hall (dormitory), Stone Hall (men's dorm-
itory), and Cassedy School (primary and inter-
grades). The Sluder School (for boys' industrial
building), the De Forest Chapel, and the Seaboard
Air Line railroads, are east of Pensacola, Fla., and
163 miles Jacksonville. It is in an agricultural,
fruit-growing region and ships con-
veniently. The chief industries are cotton
crops, cotton gins, railroad shops, novelty
and cigar factories. There are 10
six of which are for the colored
students. The educational institutions are Florida
College for Women which has a school
attached, founded in 1887; West
Seminary, University, founded in 1888;
and the Florida Agricultural College, founded in 1889.
There are three libraries. Tallahas-
see has five banks, three State banks and two
banks, capital $220,000; surplus $56,250.
An electric street and interurban railroad was
granted in 1915. It is about 220 miles long and
navigable for 100 miles.

TALLAHASSEE—TALLEYRAND-PÉRIGORD

TALLAHATCHIE, tál-a-hāch'ı, a river
which has its rise in Tippah County, in
northern Mississippi, flows southwest, and enters Greenwood with the Yocoma to form the Yazoo
River. It is about 220 miles long and
navigable for 100 miles.

TALLAHATCHIE, Battle of, in the War
of 1812. When news of the massacre at Fort
Mims (q.v.) 30 Aug. 1813 reached Nashville,
Tenn., Gen. Andrew Jackson (q.v.) collected
2,500 infantry and 1,000 cavalry, crossed Tennes-
see into what is now Alabama, on 23 Oct.
1813 established a camp called Fort Deposit
and early in November reached the headwaters of the Coosa. Learning that the Indians had
posted themselves at Tallishatchee on the south
side of the Coosa, about 13 miles distant, Jackson
sent Col. John Coffee with 920 troops to
destroy them. By a rapid march Coffee reached the
Indian camp 3 November and was boldly
charged by the Indians but repulsed them and
killed all, about 200 in number, with a loss to
himself of 5 killed and 41 wounded. Jackson
then moved toward Talladega (q.v.). Consult
Brackenridge, H. M., 'History of the Late
War,' (p. 190); Foy, H. A., 'Official Ac-
counts,' (pp. 143-145); Loring, 'War of 1812' (pp.
758-763); Wiley and Rines, 'The United States'
(Vol. V, pp. 447-448); biographies of Jackson
by Parson (Vol. I, pp. 430-438); Buell (Vol.
I, pp. 302-304) and Frost (p. 132 et seq.).

TALLAPOOSA, tál-a-poo'sa, Ga., city in
Haralson County, on the Southern Railroad
near the Alabama line, about 53 miles west of
Atlanta. It is in an agricultural region, in
the vicinity of pine forests. There is considerable
industry in the vicinity and near the city are
large vineyards. Its industries are connected
with the culture and shipping of tobacco, cotton,
farm and lumber products, and mining. There
are banking facilities and newspapers.

TALLAPOOSA, a river which has its rise in
Paulding County, Ga., and flows southwest
into Alabama. It unites with the Coosa about
five miles north of Montgomery and forms the
Alabama River. It is about 245 miles long and
navigable for 40 miles.

TALLEGAILA. See MEGAPODES.

TALLEYRAND-PÉRIGORD, tál-a-rō'n (Eng.
tall-ř-ând) pā-rē-gör', Charles Maurice
de, French diplomatist: b. Paris, 13 Feb. 1754; d. there, 17 May 1838. Although the eldest of
three brothers he was, in consequence of lame-
ness, prevented from entering the army and
destined, against his will, for the priesthood.
He commenced his studies at the College d'Har-
court, continued them at the Seminary of Saint
Sulpice and at the Sorbonne, and completed
them at Rheims, where an uncle of his was
archbishop. His life of restless activity is
naturally divided into three parts: namely, from
his consecration as bishop (1789) to his hani-
ishment by the Convention; from that period to
the Peace of Paris 1815; and from the return
of constitutional government to his death. In 1788, when only 28, he was appointed general agent to the clergy, and in 1790 he was consecrated bishop of Autun. As he found his spiritual functions inadequate to satisfy his ambition, he attached himself to Mirabeau, then connected with the Minister of Finance, Calonne. Here his political career began Mirabeau recognized his ability to the highest degree. Hitherto Talleyrand, at the court of Versailles, had displayed all the qualities of a polished, witty and gallant courtier. But he now left the court party and joined the Republicans, and on the meeting of the States-General was elected deputy for Autun, and voted soon after they opened for merging the three estates into one national assembly. In vain the court tried to stop him in his career. After the storming of the Bastille he was chosen by the national assembly one of the 63 notables of the State. In the Conciergerie Talleyrand, Sieyès, and Sailly, the Society of the Friends of the Constitution, out of which the Jacobin Club afterward arose. He soon retired from it, however, as too extreme, and in 1789 founded the society known as the Club des Feuillants. Here he exerted himself for a monarchy, surrounded by democratic institutions. On 16 Feb. 1790, he was elected president of the national assembly; and on 14 July of that year, the first anniversary of the fall of the Bastille, participated in that capacity at the July festival in the Champ de Mars. About this time he was the author of various important administrative proposals, a registration scheme which was adopted, and forms the basis of that still in force in France, and a plan of a system of public education which was of great service to the subsequent assemblies which took up the problem. When the civil constitution of the clergy was framed he gave his adhesion to it and he ordained the first Protestant clergy. For this he was immediately excommunicated by a Papal brief, and embraced the opportunity to renounce his episcopal functions (April 1791). On two occasions in 1792 he was sent to London charged with diplomatic functions, although bearing no official position. After his return on the second occasion (August 1792), he was accused of cherishing royalist sympathies, but Danton rescued him and sent him back to London (September). But the charges against him proved foolish, and at the Convention he was placed on the list of emigrants, which precluded his return to France. His power under the Directory was now forever lost, although by the intervention of Madame de Stael the decree against him was recalled in 1795. After his arrival in Paris the opposition which he met with from Carnot prevented him from being employed, and kept him in bad odor. At last, by exerting himself in the Constitutional Club, he succeeded in 1797 in gaining the Ministry of Foreign Affairs; but he was suspected of keeping up an understanding with the agents of Louis XVI. He was obliged to resign in July 1799, and his downfall as a republican was complete. But he had early recognized Bonaparte as the coming man in France and after the latter's return from Egypt did much towards making the critical event of the 18th of November 1799 (10 Nov. 1799) when the Directory was overthrown and the Consulate began. Appointed Minister of Foreign Affairs, he took the lead in the negotiations by which the Treaties of Luneville and Amiens were concluded, in 1802. He had married a Mrs. Grand, with whom he had been living for some years. They were in 1813. He became, in the course of the Napoleonic idea, was a chief of the murder of the Duc d'Enghien, and after the establishment of the empire in 1804 was appointed to the office of chamberlain. In December 1805, after the conclusion of the campaign against Austria he negotiated the Peace of Presburg; and following year exerted himself for the election of Louis Bonaparte to the Dutch throne. On 6 July 1806, he was created Prince of Beaulieu. After the battle of Friedland, he decreed a Royalist committee, and in conjunction with Fouche began to intrigue for Napoleon's fall. From this time on, the issue of the Russian expedition, he placed himself in communication with Louis XVIII, the Congress of Châtillon, received the congress of Russia into his hotel, and on 1 April established a provisional government, himself at the head of it, and procured Napoleon's abdication. He afterward exerted himself very effectually in re-establishing Louis on the throne of his ancestors. He was at Congress of Vienna when news arrived that Napoleon had landed from Elba. He took an active part in the declaration then issued charing Napoleon as a disturber of the peace. In 1815 the Allies again entered Paris. I became president of the council with the office of Foreign Affairs; but as he resigned the second Peace of Paris he gave resignment. With the commencement of consular government in France and the internal connected with it Talleyrand's principles were properly concluded. In the first years of the Restoration he often appeared at court and gave good counsel, of which the court profited; but as he often voted with the opposition, defending freedom of the press, and condemned the English campaign of 1823. When he saw the rocks on which the nation would be wrecked, he retired from public life, keeping open house, and giving a reception to all who had distinguished themselves either by literary or political servitude, with his social intercourse Talleyrand always relished the grandeur of old times. Not indolent he worked as little as possible. He was well acquainted with the art of others to account and get them to work. In ordinary business he was more ease, and skillfully skimmed the surface of things, but he did not hesitate to speak on the spur of the moment or in important emergencies. Probably this is why he adopted the adoption of one of his favorite axioms, never to explain one's self. He was accustomed to say,
been often said long before him, usage had been given to man to en-
to conceal his thoughts. On the occas-
a, atROb to the breach in his belief.

Louis Philippe, however, cepting the throne, asked his advice, vied the short answer that he should When, by the revolutions in Belgium ed, in connection with other circum-

th great distinction, and rendered by the an oracle. It is said that before his was reconciled with the Church. The part of his immense property, esti-about 18,000,000 francs, he left to his 
Duc de Dino. He left memoirs tint which were to remain unpublished rs after his death. They have proved value. Consult 'Correspondence Be-
leyn and Louis XVIII1' (1881); e, 'Mémoires Politiques'; Blanc, 'His-
Dix Ans'; Guizot, 'Mémoires'; and, isset, 'Talleyrand' (1894); McCabe, lleynard (London 1900).

TALLIEN, Jean Lambert, zhôn läô-bär
French revolutionist: b. Paris, 1769; d. Nov. 1830. He first made himself nown by publishing a revolutionary alled Ami de Clatory. He soon became he most popular men of the revolu-
arity, and was concerned in the common 10 Aug. 1792. Nominated a deputy to etion from the department of Seine he distinguished himself in that body boience in the process against Louis n objecting to the king's being allowed a defend him. He took part in most guinary proceedings which occurred he ascendency of Robespierre, and sent on a mission to Bordeaux. Here reeked in his sanguinary career by the of Miss de Fontenay, a woman re- for her beauty, who, having been im-
at Bordeaux as she was going to join y in Spain, owed her life to Tallien. her with him to Paris, whither he let, and bore himself before the Convention he charge of moderation. After the ant and his party, Tallien perceived should become one of the next vic-
obespierre if he did not strike the first blow. Accordingly, at the sitting of the Convention of the 9th of Thermidor (27 July 1794) he vehemently assailed Robespierre, and it was od that the influence of his friends was brought to the guillotine. At this period he married his protégée, Madame de Fontenay. Having been nominated a member of the committee of public safety, he used all his influence against his former associates, Fou-
quiere-Tinville, Carrier, Lebon, etc. an demanded the suppression of all the revolution-
ary committees. In 1795 he was sent as commissioner of the Convention to the army of Hoche in Brittany. He subsequently became a member of the Council of Five Hundred, but his influence gradually 'declined. In 1798 he ac-
accompanied Bonaparte's Egyptian expedition. The vessel in which he sailed to return to France was captured by the British, and he was taken to London. On finally reaching France he found his importance altogether gone, and was glad to accept the office of French consul at Alicante. The last five years of his life were spent in poverty in Paris.

TALLIS, or TALLYS, Thomas, English composer of cathedral music: b. about 1514; d. 23 Nov. 1555. He was the author of some of the finest chants in the cathedral ser-
ice of the English Church, and filled the position of organist of the chapel royal in the reigns of Edward VI, Mary and Elizabeth. William Byrd, the distinguished musician, was his pupil, and the two published in 1575 a collection of motets and hymns. Tallis composed settings to the 'Venite Exultemus,' 'Magnificat,' the 'Nunc Dimittis' and other canticles and to the 'Te Deum' as used in the English service, and his works fill a large space in the church music catalogue of Novello.

TALLMADGE, tâl'máj, Benjamin, American soldier; b. Setauket, N. Y., 25 Feb. 1754; d. Litchfield, Conn., 7 March 1835. He was gradu-
ated from Yale in 1773 and became principal of a high school in Wethersfield, Conn. He en-
listed at the outbreak of the Revolution and rapidly attained the rank of major. In 1779 he crossed Long Island Sound and captured 500 Tories at Lloyd's Neck, L. I., and in 1780 suc-
scessfully planned the capture of Fort George at Oyster Bay. He was given command of the Major André and had charge of his execution. Later he settled in Litchfield, Conn., and was me-
ber of Congress from 1801-17. Consult 'Memoirs' by his son (1859).

TALLMADGE, Nathaniel Pitcher, Amer-
ocian legislator: b. Chatham, N. Y., 8 Feb. 1795; d. Battle Creek, Mich., 2 Nov. 1864. He was gradu-
ated (1815) at Union College, then studied law and (1818) was admitted to the bar. He commenced practice at Poughkeepsie, and was sent to the assembly in 1828, serving as State senator from 1830-33, when he was elected to the United States Senate. He was appointed by President Tyler governor of the Territory of Wisconsin in 1844, retiring within a year from office and practising his profession at Fond du Lac. His last years were spent at Battle Creek, Mich.

TALLOW, a somewhat indefinite mixture of the harder and less fusible fats, which is chiefly prepared from the natural fat of sheep and omen. It consists mainly of stearin, olein, and palmmitin, and it is nearly colorless and taste-
less when pure, although the commercial product is commonly yellow. Until the cellular tissues are removed it is termed suet. In the manufacture for tallow, the solids are cut into pieces and boiled with water, the fatty matter then melting and rising to the surface, whence it is removed by skimming. The cellular tissues of the natural fat remain behind, sensibly unaffected; but they are afterward treated by great pressure, to express whatever tallow they may have retained after treatment by the boiling process. The whiter and purer portions of the tallow are used in the manufacture of candles, and the softer and yellower grades are used in the manufacture of soap, as well as for dressing leather, and as a lubricant for heavy machinery. The melting point of tallow varies with the composition of the substance, commonly ranging from 100° F. to 120° F. The specific gravity is usually about 0.93.

**TALLOW, Mineral**, a waxy solid formed of a mixture of the higher hydrocarbons, usually of the paraffin or methane series. Commonly called tallow to indicate a false or impure composition, it may be considered a solid petroleum. It occurs in irregular seams and masses in the earth, in Galicia, in the Caucasus, and in Colorado. After purification it gives a product called cetesine, very similar to beeswax in physical properties. It is used in the manufacture of candles, of insulating materials, of bottles to contain hydrofluoric acid, and as an adulterant for beeswax.

**TALLOW TREE**, any of several trees which yield rather dense fatty substances used like tallow for making candles and soap. The tallow tree or butter-and-tallow tree of Sierra Leone (Fouadelma butyracea) is a member of the family Guttiferae; the oil obtained from its fruit is used like butter. The tallow-tree of Malabar (Fouadica indica) belongs to the family Dipterocarpaceae and is noted for its large leafy leaves sometimes 10 feet long. Its panicles of fragrant white flowers, for the hard, white, scentless tallow of its seeds, and for the "East Indian copal" which is obtained from incisions made in its large trunks. The candlemaker of Matto Grosso in Brazil and in America the tallow tree of China (Napium schiffrum), a member of the family Euphorbiaceae, is probably best known. It has become naturalized in the Southern States, having been introduced in the vicinity of Charleston and Savannah whenever it has extended. It is a large tree with long-stemmed, smooth, ovate pointed leaves, about two inches long; inconspicuous flowers in straight terminal spikes; and hard, smooth, brown three-celled capsules about half an inch in diameter. The hemispherical seeds are covered with a white waxy tallow, and after the capsule bursts hang by threads among the bright red leaves of autumn. They are gathered by the Chinese, crushed and boiled (the capsules also), and the tallow skimmed off. Wax is manufactured from tallow the animal fats are cut three pounds to 10 being the usual proportion. But arts this tree has furnished the Chinese with their candles. Vermilion is often added to color the otherwise white wax.

**TALQVIST, talekvist**, Knut L., Swedish Orientalist; b. Kyrkoslät, 16 March 1865. He studied at the Swedish Normal Lyceum and the University, Helsingfors, then at Leipzig and Berlin. Student was candidate in philosophy (1887), and (1890) and rector of the school of Assyriology and Semitica (1891-99) becoming professor of literature in the latter year. He wrote Sprache der Contract of Nabunaid (1861), Babylonische Schenkungsbriefe (1891), assyrische Briefe (1891), "Arabische Sprichwörte und Spiele" (1891), "Ibn Sa'd Kitab almugrib, Book IV" (1891), and Neubabylonisches Namenenbuch" (1905).

**TALLY**, a stick divided into two halves, formerly in general use as a medium for recording accounts. One-half was kept by the debtor and one by the creditor. When any debt or payment was recorded the two halves were adjusted together, and a new mark made on them both; the method, however inconvenient in other respects, was an excellent security against forgery, it would be difficult, if not impossible, for the creditor to make a false tally corresponding to the counter-tally, in all respects in which the creditor wished them to correspond; so, as not to be detected as false. When a tally was entirely cleared off, the creditor's tally was given to the debtor. Tallies were in use till the 18th century for keeping accounts in chequer of England. In modern usage a tally mark made to record a score may be called a tally.

**TALMA, Francois Joseph, frän-svæ zef tal-ma**, French tragedian; b. Paris, 15 Oct. 1763; d. 19 Oct. 1826. In 1787 he made his début at the Theatre Francais in the character of Seide in Voltaire's Mahomet and was received with applause. Talma rendered an important service to the French stage by introducing dressing in accordance with the time and country of the character represented. Chénier's tragedy of Charles IX, which was brought forward in 1786, and Talma, after studying the character of Charles in history, his person in medals and portraits, excelled in their such truth and life that his realization as the first French tragedian was established beyond dispute. The principal work which he created, or carried to the highest perfection, were Seide, Othello, Hamlet, S Regulus, the grandmaster of the temple of Cestis, Charles IX, Charles VI, Manlius and Or He did not generally excel in comedy. He appeared in 1823 with great success in the character of Danville in Delavigne's "Ecole des Vieillards." Talma was the great favorite of the Emperor Napoleon and accompanied him to Erfurt in 1808 and to Dresden in 1813. He was the author of the very interesting work, entitled Reflections sur Lecain et l'Art Théâtral, and of an autobiography afterward edited and published by Dumas (1849-50).

**TALMAGE, James Edward, American geologist and theologian; b. Hungerford, England, 21 Sept. 1862. In 1876 he emigrated to Utah with his parents who had embraced the...**
of the Latter-day Saints. He was a student at Lehigh University 1882–83; at Johns Hopkins University 1883–84, and was graduated in chemistry from the former in 1891. He received a D.Sc. from the same university in 1912; also honorary D.Sc. and LL.D. degrees from Church of Jesus Christ of Latter-day Saints in 1889. He was professor of geology and geophysicist at Brigham Young University 1884–88; president of the latter institution 1898–99; president of the University of Utah 1894–97; professor of geology and mineralogy and director of the Desert Museum, Salt Lake City 1892–1917. He was one of the delegates from Utah to the Royal Society of Edinburgh of the Congress of Natural Science, Russia, in 1898. He was ordained deacon 1887, teacher 1889, and held the higher offices of the church.
terizations: of "our sulky, sullen dame, nursing her wrath to keep it warm"; of Souter Johnny, "his ancient, trusty, drouthy crony"; of Tam himself, "the heaving, blustering, blathering, bellum." And as in 'Tam o'Shanter' the imagination of Burns is unmarrled by the moralizing and sentimentalizing that so often besets him, so the style, terse, racy, picturesque, illustrates his mastery over his native idiom. Burns himself said of this poem that it "showed a finishing polish" that he "despaired of ever excelling." And we may echo his verdict that the unique quality of 'Tam o'Shanter' is one that he never did excel. Consult Henderson, T. F. (in 'Cambridge History of English Literature'), Vol. XI, and bibliography.

FRANCES W. CUTLER.

TAM-SUI, tám-soóč. Formosa, a seaport on the northern coast of the island at the mouth of the Tam-su River, 10 miles north-west of Tai-pe, the capital. It is the chief export town of the island, and the principal staples are tea, rice, sugar, coal, jute, camphor, etc. Pop. about 7,000.

TAM-TAM, tám tám. See Tom-tom.

TAMA, tâ'ma, Iowa, city in Tama County; on the Iowa River, and on the Chicago, Milwaukee and Saint Paul, and the Chicago and Northwestern railways, about 63 miles north-east of Des Moines and 18 miles east by south of Marshalltown. It is in an agricultural and stock-raising region. An Indian reservation (Sac and Fox) is nearby. The chief manufacturing establishments are flour mills, paper and lumber mills, broom factories, machine shops and cigar factories. The shipments consist chiefly of flour, brooms, poultry, livestock, eggs, vegetables and grain. There are seven churches, public and parish schools, two banks and a library. Pop. 2,900.

TAMAGNO, Francesco, Italian operatic tenor: b. Turin, 1851; d. Varese, 1905. His début on the operatic stage occurred (1873) in 'Un Ballo in Maschera,' at Palermo. Under Abbado he appeared on the New York stage in the season 1889-90 when his name in Europe was a word to conjure with among his patrons. Under Abbado and Grau, season 1894-95, he was again on the boards in New York at the Metropolitan Opera House and Americans were treated to his renderings of 'Otello,' his greatest rôle, which had made such fame in Milan. He retired from the stage in 1902.

TAMANDUA. See Ant-eater.

TAMANOIR, the great ant-eater (q.v.).

TAMAQUA, tâ-mâ'kwa, Pa., borough in Schuylkill County, on the Little Schuylkill River, and on the Philadelphia and Reading, and the Central of New Jersey railways, about 32 miles north of Reading and 15 miles west of Manch-Tunk. It is in a region noted for the quantity and quality of coal deposits. It was settled in 1790, and became a borough in 1853. The chief manufacturing establishments are flour mills, tanneries, machine shops, a powder mill and planing mills. It has large coal yards. There are about 20 factories, paying wages, exact $400,900 annually, with product of over $1,000,000. There are 12 churches, a high school, elementary schools, a business college and a library. There are several banks and newspapers. Pop. 10,000.

TAMAR, tâ'mar, (1) a southern river of England, flowing between the counties of Cornwall and Devonshire; and emptying through the Hoo Moase into Plymouth Sound, and is navigable above Plymouth; length about 60 miles. (2) A river of Tasmania, formed by the union of the North and South Esk, and flowing into Bass' Straits at Fort Dalrymple.

TAMARACK. See LARCH.

TAMARAO, a sturdily built dwarf buffalo (Bos mindorensis) of the Philippines, which stands about three feet and one-half feet high at the shoulders and has coarse, thick, blackish brown hair. "The horns," says Lydekker, "although massive, are comparatively short, and rise upward in the plane of the face with a lyre curvature; they are distinctly triangular, with the largest face in front, and are somewhat roughened. In its massive horns, thick legs and uniform coloration, this species comes nearer to the Indian buffalo than to the auro.

TAMARIND. See MARMOSET.

TAMARIND, a leguminous tree (Tamarindus indica) and its fruit. It is supposed to have originated in eastern tropical Africa, but is now universally cultivated in the tropics. It reaches a height of 80 feet, and has a crown of spreading branches and thick foliage. The leaves are abruptly pinnate, the flowers fragrant, red and yellow, with three perfect petals and four sepals and colored caduceus bracts. They are gathered in terminal racemes. The bean-like fruits are indehiscent flattened pods, and have a brittle brown shell. The seeds are flat, angular and shining, and embedded in a dark-hued fibrous juicy pulp, which is pleasantly acid, laxative and cooling. This fruit is used to prepare tamarind fish, to make acidulous cooling drinks, and is also a spice of commerce; with or without being preserved in sugar. Every part of the tree is used for medicinal purposes, except the yellowish-white, purple mottled wood, which is valuable for turnery, being hard and heavy. The seeds are astrigent, the leaves are employed for curries and for a yellow or red dye. "Velvet" or "black" tamarinds, or black tamarinds, are the product of a small leguminous tree (Dialium guineense), of Africa. It has pinnate leaves on slender branches, and downy black pods, of about the size and shape of a hazel-nut, containing seeds embedded in an edible, farinaceous pulp. The tamarind of New South Wales is a slender sapineceus tree (Cupania anacardioides) of Australia, has an acid fruit and coarse-grained, whitish wood. The wild tamarind is a large tree of Jamaica (Pithecolobium fliciolium), having twice-pinnate leaves; Pithecolobium dulce is the sweet-pulped Manilla tamarind, Certain leguminous trees of Central America and the West Indies, Pentaclethra malacotica and Adenanthera pavonina, are respectively the wild and the yellow tamarind.

TAMARISK, any member of the genus Tamarix which is represented by shrubs, also called "flowertine cypress," inhabiting warm and dry lands, but not hardly in America as far north as Massachusetts. They are salt-loving plants, often growing near the sea that the spray of high breakers dashes over them, and are
Admireable for maritime planting, ne other plants living near salt-water, id steppes, certain species of *Tamarix* age with a punctate appearance, caused te salts. These leaves excrete saline, which in rainless seasons serve to moisture during the cool nights, and its absorption by special cells at the of the tiny cavities. In the daytime, salts cover the leaves with a crust, which protects the plants from excessive ion under the desert sun. The tama-tree (*T. articulata*) of the Indo-region is a bush or small tree looking it like a conifer, which secretes enough water useful in a culinary way; it is also source of tamarisk-galls employed for medi-for dyeing, since they contain 50 per tannin; also an astringent bark.

Risks are generally planted for ornamental purposes, and are somewhat larger than in cold winters the ground. They are of unusual type, with widely spreading, some-thing-like branches, crowded with small k scales. In the axes of these are formed branch-buds, so that the plant exudes new shoots. The flowers are pink, in close spike-like racemes are often panicked, and are softed by protruding stamens. One of the known (*T. gallica*) reaches 15 or m height, with panicked racemes bloom-ete in summer; it is very easily propagated nishes good firewood. A species of the (*T. ×mannifera*) when punctured by a insect (*Coccus manniferus*) exudes honey-sap of sap that harden in the morning; this is gathered and sold to Syrian as manna (q.v.). The German tama- *Myricaria germanica*. It has a wand-like, bluish foliage, and many racemes of k flowers, terminating lateral branches.

*TAMATE*, tä-mä-tāv, the capital of car, situated on a peninsula slightly the middle of the east coast. It is the port of the island and has a good protected by a natural breakwater, and are. A railroad connects it with the rest of the islands, so also canal transportation. Hides, gold a and raffia are the leading articles of trade. There is cable communication with there, Mauritius, Reunion and Aden. re good banking facilities. Pop. 8,647.

*TAULIPAS*, tā-mow-le-pās, Mexico, a the Gulf coast, occupying the north-ermost part of the country. Its area is around 20,000 square miles. The southwestern part is traversed by the eastern Sierra but the greater portion belongs to the coastal plain and a rolling country, gradually to the coast. The latter is h lagoons and sand-bars. The state is by several large streams, and the Rio forms the northern boundary. The cli-climate is hot, and the northeastern e shore is subject to heavy rains on the lower mountain slopes, where is sufficient. There are three railway agriculture and grazing are the chief s. Cotton, sugar and cattle products ried. Tampico (q.v.) is the chief se- seems for steamships connect with Pensa-cola, Baltimore, New York and Havana. The capital is Ciudad Victoria. Pop. 249,641.

*TAMAYO Y BAUS*, tā-ma-yō ē ba-ous, Manuel, Spanish dramatist: b. Madrid, 1829; d. 1898. His parents were actors and the boy traveled about with them and early learned to play his parts on the stage; and thus early gained an insight into the nature and structure of the drama. The natural result was that he soon began writing dramas himself. His first dramatic production, an adaptation of 'Genevieve de Brabant,' was produced successfully when he was only 11 years of age. In this play his mother and himself took leading parts, the first production taking place in Granada. From this time on he continued to write for the stage and to acquire an increasing reputation as a dramatist. At his retirement from this elected a member of the Spanish Royal Academy, and for the last 14 years of his life he was director of the National Library and chief of the board of archivists, librarians and antiquarians. Among his best-known dramas are 'La locura de amor' (1855); 'Lances de honor' (1863); 'Un drama enojado' (1867). The latter, which has been translated into English under the title of 'A New Drama' by J. D. Fitz-Gerald and T. H. Guild (New York 1915) is considered his best drama. Consult Cotarelo y Morl, E., 'Historia Literaria' (Vol. I, Madrid 1901); Sicarás y Salvador, N., 'Manuel Tamayo y Baus' (Barcelona 1906); Tonnenberg, Boris de, 'L'Espagne littéraire' (Paris 1903).

*TAMBERLIK*, täm-ber-lek', Enrico, Italian operatic singer: b. Rome, Italy, 16 March 1820; d. Paris, 15 March 1889. He began his career at Naples as tenor singer in 1841, and in 1850 went to England, where he enjoyed great popularity for 24 years. He visited the United States in 1857. After his retirement from the stage he lived in Madrid, where he engaged in the manufacture of small arms.

*TAMBON*, täm-bo-bōng, Philippines, pueblo, province of Rizal; in the northwestern part of the province, near the coast of Manila Bay; five miles north of Manila. It has a large sugar reinery and a cotton factory; there is also weaving of cotton cloth and the fisheries are also important industries. It is connected with Manila by steam tramway, and carries on a considerable trade. Pop. 25,000.

*TAMBOUR-WORK*, a species of embroidery introduced into Great Britain in the 18th century, now little used. A single tambour worker usually sits at a low circular frame, over the top of which the silk, linen or muslin is stretched by means of a hoop, much in the same way as the head of a drum is tightened. A frame of different construction is used when several workers are employed on the same fabric, consisting principally of two rollers, which, when properly fixed, stretch the linen, etc., to the necessary degree of tension. As the work proceeds the finished part is wound on one roller, while a third surface is at the same time unwound from the other. The needle, which is about one-half inch in length, terminates in a small hook with the point curving inward. This is fixed in a handle of bone, ivory or wood, of the thickness of a quilt, by means of a small screw on the side. The
TAMBOURA—TAMING OF THE SHREW

worker, holding the thread on the under side of the frame, passes the needle through the muslin, etc., from the upper side, and by a continued series of loops interwoven together, succeeds in making a beautiful chain-like, with which she traverses the outline of any pattern previously sketched upon the fabric she is employed to ornament.

TAMBOURA, the name applied in Persia and Turkey to a musical instrument of the guitar type, with strings of wire struck with a plectrum. The neck is long and the body, of gourd-shape, is often beautifully ornamented.

TAMBOURINE, tám-boor-ón', a musical instrument of the drum type, much used among the Italian peasants and negro minstrels. It consists of a piece of parchment stretched over the top of a broad hoop, which is furnished with little bells. It is sounded by sliding the fingers along the parchment or by striking it with the back of the hand or with the fist, elbow, etc.

TAMBOV, tám-bóf', Russia, capital of the government of that name, on the left bank of the Tzna, at the confluence of the Studenets, 203 miles by rail southeast of Moscow. It was founded in 1626 and was first fortified, and is yet surrounded by a dilapidated rampart, and is built chiefly of wood. It has a gymnasium, military school, ecclesiastical seminary, female institute, house of correction and infirmary; is the residence of a governor, the see of a bishop and the seat of several important courts and public offices. There are breeding studs, manufactures of woollens and sailcloth, leather, soap, tallow, alum and vitriol, and a considerable trade with Moscow and Petrograd in tallow, leather, wool and provisions. Pop. 71,400. The government or province is 25,710 square miles in area and the population (1915) is 3,555,000. It is a rich agricultural region.

TAMERLANE, tám-ér-lán'. See TIMUR.

TAMIL, or TAMIR, a branch of the Dravidian stock to which the original inhabitants of India belonged. They inhabit the extreme south of India, and have remained comparatively free from admixture with the Sanskrit-speaking Indo-Europeans and other invading races of subsequent arrival. Retaining their own tongue they adopted and developed the civilization of their conquerors and are much more enlightened than other races of Dravidian stock. The Tamil language is spoken over a large section in the extreme south of India; it is spoken to a great extent in Ceylon; it is spoken also by a majority of the Indian settlers in places farther east, as Pegu, Penang, etc.; and in many parts of southern India, even where it is not the vernacular, it is spoken by the better class of Hindus. The structure of the language is very simple. It has two dialects: the higher (Shen-tamil), now used in poetry, is the more ancient of the two; the lower (Kodin-tamil) is the language of common life. The literature of the Tamil language, the earliest extant works of which are supposed to be as old as the 9th century of our era, embraces not only every branch of the knowledge of northern India. Consult Pope, 'First Lessons in Tamil' (Oxford, 7th ed., 1904). See INDIA.

TAMING OF THE SHREW

Taming of the Shrew has been immensely popular Shakespeare's and is still notably successful on the stage. There is little evidence of the date at which it was composed or Shakespeare's concern in it. It was in the 1623 folio, but a separate quarto in 1631 shows its continued time when few but the very great Shakespeare plays justified publication. This drama is a refreshment of the best pre-Shakespearean co Taming of A Shrew, printed in characters are renamed (except Kate, lines wholly rewritten, but the general plot of the is not radically altered, more in the last regard appearing in the Bianca than in that of Katharine. effort to ascribe to Shakespeare 'Taming of A Shrew' is invalidated fact that the former play below Pembroke's company and by its joines from Marlowe, legitimate is limited to discussion of the ex poet's revisionary work in preparing Taming of the Shrew. That the Petruchio scented is not beyond many critics the scene of the lovers of Bianca to an unknown reviser. No particular reason for supposition exists beyond the unwilling credit Shakespeare with work not beyond his abilities of the manuscript. This, of course, is a correct criterion: it is clear that the author is exerting power. In the case of the present logical to suppose that the entire revision done by Shakespeare, who handled plot with enthusiasm and retouched ordinate scenes with independence, quacy, but in a somewhat perfuncto. The notable Induction, with the character Sly, is not primarily Shakespeare's creation; it occurs in the earlier version indeed Sly continues on the stage throughout entire performance and offers elements like that of Revenge and Ghost in 'The Spanish Tragedy.' Shal apparently in the interests of allows him to be forgotten by the of Act I, but he has made the Induction of his own by the insertion of shire place names and allusions. On 1633 'The Taming of the Shrew' was Saint James' Palace before Charles I, queen. It is noted that the play was Two nights later it was followed by formance of Fletcher's sequel, 'The Tamel,' in which Petruchio's second with the tables. Various adaptations of the play were popular in the 17th centuries. In 1754 Garrick produced act abridgment called 'Katherine: a chio,' which for a century or more the original. The complete play by Augustin Daly in 1887 with success. John Drew played Petruchio On other Lucentio and Ada Rehan. Katharine hundred performances were given between January and 13 April.

MMANY HALL. See Tammmany So-

MMANY SOCIETY, or COLUM-
ORDER, The, was founded 12 May
by William Mooney, ex-Revolutionary
(two weeks after the national govern-
ment was established), as a fraternity of
those who conceived to be independ-
ent, popular liberty and the federal union
country. It had for its objects (1) the
ity of democratic-republican institu-
tions and others of its members, "their
i and orphans, and others who may be
objects of their charity." The member-
as composed of those who were known
the Revolution as "Sons of Liberty"
Sons of Saint Tammany; societies
promote the cause of independen-
society was opposed to the Saint George,
David and Saint Andrew societies, whose
members openly proclaimed fealty to
III. After the Revolution, Alexander
on (q.v.) removed the political disabilities
for the New York Loyalists and they became
the Federalist party, and being
fought corruptly for Hamilton's
me of a Federal President and Senate,
office for life, who should appoint the
governments and dominate Congress.
3. These Loyalist Tories were elevated to
immediately on their enfanchasement.
ragged the "Liberty Boys" who fought
soldiers, and suffered repeated be-
these same Loyalists whose plots were
against the patriots. Many of these Tory
aces were successful and sent numbers
into the charnel prison ships to meet
others failed, as when the Tory mayor
York, Mathews, plotted to kidnap
rgate and assassinate his staff. The
broad by these and kindred infamies was
fire by the disfranchisement of
onary soldiers whose means and prop-
erie meagre. In 1777 the constitutions
and the constitution of New York State
to the value of 100 pounds, free of
its. This gave full political power to
Loyalist Tories who monopolized trade
ning privileges, while it disqualified the
those who fought in the patriot army
and property. The Cincinnati (q.v.)
to the existence of bitterness and hatred,
and others pointed out its menace to
ries of the people and its monophasal
found an order of hereditary nobles,
nitarianism as a basis. The Tammany
as a crowning protest to
portentous happenings and to discredit
Hamilton's prophecy that the democ-
republican scheme of government was
led to disastrous failure.

y History.—The Tammany Society was
into 13 tribes corresponding to the 13
States. The Society adopted Indian
and ceremonial and the forms and usages
adapted to the fullest extent practical.
igwam was the term applied to the So-
place of meeting. Indian symbols and
mottos were used to designate the 13 tribes,
as follows:
The Eagle Tribe, New York State.
The Otter Tribe, New Hampshire.
The Panther Tribe, Massachusetts.
The Beaver Tribe, Rhode Island.
The Bear Tribe, Connecticut.
The Tortoise Tribe, New Jersey.
The Tiger Tribe, Delaware.
The Kattinsunk Tribe, New Jersey.
The Fox Tribe, Maryland.
The Deer Tribe, Virginia.
The Buffalo Tribe, North Carolina.
The Raccoon Tribe, South Carolina.
The Wolf Tribe Georgia.

The 13 sachems (or trustees) annually
elected a grand sachem or president. The
kitchi agnew, or great grand sachem, was
an honorary office conferred upon the following
Presidents of the United States: Washington,
John Adams, Jefferson, Madison, Monroe, John
Quincy Adams and Jackson. The office was
abolished after General Jackson's incumbency.
The Sagamore was the master of ceremonies
and the Wiskinskie the sergeant-at-arms.
According to the true Indian fashion the year
was divided into seasons and these subdivided
into moons. The era began with the discovery
of America by Columbus and included the year
of the Declaration of Independence and
of the founding of the Society. (New York City, 3
Dec. 1803, is written by the Society thus:
Manhattan Season of Snows, 12th moon, year of
discovery 411th, of Independence 127th and of
Institution 114th). The Society motto is "Freedom
our Rock." The following toasts at the
4 July 1789 banquet illustrate the Society's
sentiments from its formation. Thirteen cannon
shots followed each toast. These are the two
first toasts: (1) "May honor, virtue and patri-
that character ever be the distinguished
Sons of Saint Tammany." (2) "The
head men and chiefs of the Grand Council of
the Thirteen United Fires — may they
convince our foes not only of their courage to lift,
prudence to direct, and clemency to withhold the
hatchet, but of their power to inflict it in their
country's cause."

Achievements.—The national government
repeatedly failed to conclude a treaty of peace
with the warlike Creek Indians whom the Fed-
eral government was anxious to placate. The
Tammany Society undertook the conciliation.
The Celtic half-breed chief McGillivray, who
led the Creek tribe of Indians, with 28 of his
chiefs and warriors were brought to New York
by Tammany and given a banquet 2 Aug. 1790.
The Tammany braves were in full Indian
costume when they escorted McGillivray and his
warriors to President Washington. The treaty
was signed 13 Aug. 1790. The Society in June
1790 founded a museum for "the preservation,
collection, and study of Indian relics, etc." In
1791 the Society, under the direction of John
Pintard, its first sachem, founded many edu-
cational and progressive institutions which later
developed great efficiency under the Society's
fostering care. Two of these institutions have
since merited national recognition, namely, New
York Historical Society (q.v.) and the Acad-
emy of Design (q.v.). In 1793, when France in
desperation struggled to overthrow feudal op-
pression, the Tammany Society's sympathy and
moral support was prompt, enthusiastic and
enduring. Sentiments and sympathies of politi-
cal and other associations were usually expressed
by toasts at a banquet specially held for that purpose. Until about 1840 these "public dinners" were the chief means of announcing the policies, boroughs and candidates of political and social bodies. On 12 May 1793 the Tammany Society, at its annual dinner, gave the toast, "Success to the Armies of France, and wisdom, concord, and firmness to the Convention." This was followed by roasting, by roasting for many minutes. The society suffered a flood of vituperation, abuse and threats of grave harm from the Tories and Federalists. In 1800 the society bought real estate collectively to comply with the property qualifications imposed on the voter. On 13 April 1808 the society marched in a body to Wallabout ("Wallabout") Bay, where the foundation stones were laid by them of the receiving vault, for the bones of 11,000 patriots, victims of England's brutality. The society collected 11 hogheads of bones along the beach of Wallabout Bay of those who died of hunger, disease and cold in the awful English prison ships. Tammany interred these bones in a tomb near the present navy yard with imposing military honors. In 1809 the Tammany Society loudly called for war with England, pledging their lives, fortunes and sacred honor in support of the government for the waged of that just and necessary war. At every stage of the conflict the Society gave full and loyal support. Tammany Hall in Nassau street became the headquarters of the war party where they hoisted the flag to proclaim each victory and celebrated the success of the American forces. Tammany also gave a fighting force to the nation, which developed later three able generals and a colonel. In August 1814 about 1,200 members of Tammany Hall went in a body to Brooklyn and erected earthworks and other defenses. On 29 June 1814 members of the Tammany Society mobbed a large Federalist meeting gathered to celebrate the return of the Bourbon dynasty to the throne of France. In 1817 the Society with high patriotic speeches and ceremonial made into the inaugural of General Hall Farrar in Saint Paul's churchyard. On 23 Feb. 1819 Tammany gave a banquet in honor of Gen. Andrew Jackson at which they launched a boom in his behalf for the Presidency.

Manhood Suffrage.—From the moment of its foundation in 1789, the Tammany Society fought for manhood suffrage and against "imprisonment for debt." On 1 Dec. 1820 a Tammany Hall mass meeting resolved: "That the distinction of the electoral rights; the mode of appointment to office and the union of the judiciary and legislative functions were objectionable and highly pernicious." The meeting urged the legislature to pass the reform measure and advocated and when the legislature overwhelmingly advocated the extension of the suffrage. Tammany celebrated the victory for reform 14 June 1821, at Tammany Hall with democratic jubilation. The sentiment dominant at this gathering is tersely expressed by one of the resolutions: "We will not be ruled by a man without an estate than by an estate without a man."

On 4 March 1822 a banquet was given at Tammany Hall for the purpose of expressing their thanks to the many who rallied to the right of suffrage and the abolition of those cumbersome relics of old centralizing methods, the Council of Appointment and the Corporation Acts. The function of the former expressed in its title; that of the latter to give final approval or disapprove legislation. The "Toasts" at this banquet appropriately express the Tammany sentiments of the participants. Here are two: "The right of suffrage—corruption in office must be fought, most to hate for a few years to a few. This was another: "The noble and rising politician—may integrity guide him—studying the public not popularity." The extension of the right of suffrage greatly increased the voting of Tammany and augmented its political strength. In 1820 manhood suffrage in full a fact; Tammany's political power had increased, in this year Tammany succeeded in abolishing the last vestige of property qualification to the right of suffrage by an overwhelmingly large popular vote. In 1826-27 the Tammany Hall forced the fever for the five-year limit on the acquisition of citizenship. In 1827 many delegations visited General Jackson in Orleans to press the Tammany case for the famous battle in which he triumphed, and to urge his candidacy for the presidency in the coming year. Martin Van Buren, who was a member of the Tammany Hall, visited New York later in the year to realize the sentiment of the Society for the ticket. To offset this sentiment, the Tammany ticket, and the tall vote of Tammany, the "Native American" was formed, whose battle cry was "Liberty, property and the rights of the people of the country." In 1828 Tammany carried General Jackson nearly 6,000,000 majority ticket of over 25,000. This was the national election held wherein the State of New York chose presidential electors by popular vote.

Mid-Century History.—On 26 Nov. Tammany Hall held high festival in honor of the French Revolution. President Jefferson, though in feeble health, reviewed the Tercentennial parade and later presided at the banquet given Tammany Hall at Fairlawn in Saint Paul's churchyard. On 23 Feb. 1819 Tammany gave a banquet in honor of Gen. Andrew Jackson at which they launched a boom in his behalf for the Presidency.

On 1 Dec. 1820 a Tammany Hall mass meeting resolved: "That the distinction of the electoral rights; the mode of appointment to office and the union of the judiciary and legislative functions were objectionable and highly pernicious." The meeting urged the legislature to pass the reform measure and advocated and when the legislature overwhelmingly advocated the extension of the suffrage. and real terrors and their influence
mid and greedy, Tammany elected her
in 1861, Grand Sachem William
ved to take the front a regiment com-
members of Tammany Hall, which had
its threat suppressed by the army.
This regiment, the 42d New York,
t, distinguished itself for valor in 36
and engagements. In 1864 Tammany
ined General McClellan's name at the Chi-
ization districts and subordinate state
party. General McClellan
in the ensuing election, from Tam-
hforts, a majority of over 37,600 in a
ite of about 110,000. In 1870 Tweed,
gained an ascendancy in Tammany Hall,
ed the organization to many extra-
penditures, thus bringing much scandal
igwamp. He was forced to retire
leadership and was driven out of the
prey to ruin and disgrace. Since that
ammany has ceased to stand for high
and has become emblematic of boss
policies for "what there is in it."
History.—In 1872 the reform of the
ation was undertaken by a group of
under the guidance of Samuel J.
Tammany came to the front again
Kelly as its leader. It became a
ity, State and national politics.
Mr. Kelly, Tammany largely regained
ience and respect of the Democracy.
, in 1886, Tammany was gov-
y a committee consisting of Richard
James J. Martin, Hugh J. Grant and
F. Gilroy. This government even-
the absolute leadership of Richard
. Under the influence of Mr. Croker,
, 1888 won a series of brilliant po-
ities, establishing democracy firmly
ity and State. It was due to Mr.
ful management that all of the
1 Democratic organizations in opposi-
Tammany Hall were put out of exist-
Tammany left the sole representative
ocracy in this, the greatest city in the
. In 1900, after the defeat of
ocracy in the country at large, Mr.
ceased to take an active interest in
by a hard fought municipal defeat in
1892, and the wis Nixon, a protégé of Mr. Croker's,
ined in command. Mr. Nixon's training
is for the navy. His knowledge of poli-
tics was purely academic, and his leadership
was naturally very brief. The organization
then drifted along under the leadership of a
committee consisting of Daniel F. McMahol
Louis F. Haffen and Charles F. Murphy. In
1903 Mr. Murphy assumed the leadership
the vote of the executive committee. Mayor
George B. McClellan and the entire Tammany
ticket were elected in November 1903.
He was re-elected, and in 1910 William J.
Gaynor was elected by Tammany. While Mr.
Gaynor was markedly independent, yet Tam-
many held its grip on most of New York's
political activities. In 1913 the fusion can-
didate, John Purroy Mitchell, beat the Tammany
forces, and there was a partial return to Re-
publican rule. However, notwithstanding
Mitchell's acknowledged ability and popularity,
Tammany beat him in 1917, with an almost un-
known candidate, John F. Hylan. Tammany
maintains in Manhattan probably the strongest
and best organized political machine in the
world. While there are Democratic organiza-
tions and leaders in the outlying boroughs,
they are known to be ineffective.
Tammany leaders — the very name of Democratic organiza-
ion is lost. Permanent headquarters and
leaders exist in each of the 23 assembly dis-
tricts, to handle the details like a
great army. They are in business all
year around and every day in the
aiming to maintain their hold in all the political offices
and all the expenditure of public moneys that
they possibly can. The fact that they have
been able to place many judges on the bench
as well as to control most of the executive of-
ices has at times been the subject of great
scandal. Yet membership in the organization
includes very many men of high character and
patriotism, and their influence at times is
apparent.
Tammany for many years has catered to
and largely held the votes of the poorer classes
— charity has been dispensed widely from the
district offices; bureaus are maintained to give
work to those who can be depended upon to
vote with the organization; excursions, parties
and dances are given freely; those who have a
bad habit of getting into jail for small offenses
are systematically bailed. Notwithstanding
that, members and followers have been charged
time and again with catering to vice, even dis-
cussing it and trafficking in it; with dishonesty
and wastefulness of public funds; with placing
and keeping incompetents in office, and the en-
tire list of political mistakes, weaknesses and
crimes, yet after every exposure and temporary
reform, the same old Tammany comes back to
power and dominates the politics of the world's
largest city. Consult Breen, 'Thirty Years of
New York Politics' (1899); Poore, 'Richard
Croker' (1901); Riordon, 'Plunkett of Tam-
many Hall' (1905); Forrest, J. W., 'Tam-
nany's Treason' (Albany 1913).

Tammerfors, täm'mér-fôrs (Finnish, TAMPERE), Finland, a town in the government of
Tavastehus, about 80 miles northeast of
Abo, on the railway from the Gulf of Finland
to the Gulf of Bothnia. It is the third largest
town in Finland, and the principal manufactur-
ing centre. Its industries include cotton and
linen spinning and weaving, and the manufac-

ture of paper, iron and steel mills, locomotive works and shipyards. Pop. 45,213.

TAMMUZ, täm′ūz, a Babylonian deity, worshiped by Jews who drifted into idolatry, and mentioned in Scripture, in Ezekiel viii., 14: "Then he brought me to the door of the gate of the Lord's house which was toward the north, and behold, there sat women weeping for Tammuz." According to Sayce (in Hastings' Dictionary of the Bible) Tammuz was originally the sun-god, and was a Babylonian deity whose worship was early imported into the West, the name being in Sumerian Dumuzi, "the son of life." In Canaan Tammuz was addressed as Adonai, "my lord," whence the Greek Adonis; and as Tammuz was originally associated with the Babylonian goddess Istar (Asarte), so Adonis was associated with Aphrodite. The Vulgate agrees with this explanation by its rendering of Tammuz as Adonis. This worship was much practised among the Phenicians, and was celebrated chiefly at the Phenician town of Byblus. The ceremonial was prolonged through different scenes. Adonis was supposed to have been killed by a boar; search was made for him, a wooden image being provided to represent Adonis, and on his being found, wild and licentious orgies began, and the burial of the idol terminated the first portion of the pageant. The river of Adonis, or Nahr Ibrahim, at the season of the year at which this worship took place, becomes discolored from the heavy rains on Lebanon, and in the popular superstition the stream was stained by the blood of Adonis.

The resurrection of Adonis next followed in the ritual, and was celebrated with fratricidal rejoicings. This idolatry appears to have been originally symbolic, connected with the sun's decline in the winter and his returning strength in summer, or with the death of nature and its revival in spring. The festival seems to have been held at the summer solstice. Movers and Hitzig place it at the autumnal equinox; but Tannuz is with the Jews the name of the fourth or midsummer month. Jerome also asserts that the anniversary of the death and resurrection of the fabulous Adonis was celebrated in the month of June. It was, however, in the sixth month that Ezekiel's vision happened. The period of celebration might perhaps vary, or the time of the prophet's vision might not be coincident with the actual celebration of the festival. The worship of Adonis was suppressed by Constantine. Consult Langdon, S., "Tammuz and Ishtar" (Oxford 1914).

TAMPA, Fla., city, port of entry, county-seat of Hillsborough County, at the mouth of Hillsborough River at its entrance to Tampa Bay, and on the Atlantic Coast Line and Seaboard Line railroads, being the Gulf terminus of both, about 29 miles from the Gulf of Mexico. It has a harbor, the best on the western coast of Florida, and it has regular steamer connection with all the large Gulf ports, large ports of the West Indies and with New York and a number of other Atlantic ports. In the vicinity are large mines of phosphate. Lumber and naval stores are largely produced and shipped.

Manufacturing.—The chief manufacturing industry of Tampa is connected with tobacco products. In 1914 the number of factories was over 200 (three-fourths of them being cigar factories), the capital invested $9,500,000, and the value of the product for the year $65,000,000. The wages paid to workmen are more than $5,000,000 annually. The tobacco used in the factories is nearly all imported from Havana, Cuba. The manufacturing of tobacco is Tampa is largely done by Cubans. The Sumatra "wrapper leaf" grown in Florida is said to be superior in quality to that grown in Sumatra, and is used to some extent.

Commerce.—The amount of tobacco leaf imported into the port of Tampa from Havana has for several years exceeded that of any other United States port except New York. The internal revenue paid by the city exceeds $1,000,000 annually, and the custom collections for the district are about $9,000,000. Phosphate comes next after tobacco, and over $3,000,000 is sometimes shipped abroad in a single year. The quantity of fruits and vegetables which are being shipped to Northern markets is increasing.

Buildings and Municipal Improvements.—Since 1886, when Tampa was made a port of entry, it has grown rapidly. To accommodate its late number of winter guests, many large and beautiful hotels have been erected. Other public buildings are the custom-house, the churches, the schools, the banks and many of the business blocks.

The electric car lines connect the suburban sections with the different parts of the city. The water supply comes from springs; the daily use is 7,000,000 gallons. The pumping capacity of works is 10,000,000 gallons.

Churches, Schools, Etc.—There are 8 church buildings. There are 12 public school buildings, including the Hillsborough County High School, established in 1886. Another high school is in charge of the Sisters of the Holy Name, who conduct three parish schools in Tampa and one in each of the nearby suburbs, West Tampa and Port Tampa. There is a college for boys, under the management of the Society of Jesus, and five private schools. There are three daily and five weekly newspapers. The six banks have a combined capital of $1,000,000, and deposits amounting to over $6,000,000.

Government.—The government is vested in a mayor and a city council, elected by the people for terms of two years. The council has 11 members, three being elected at large. There are police, sanitary and public works departments, including a board of health with ample powers to protect the city's interests.

History.—Tampa is the historical landing place of Narvaez and De Soto, of ill-fated early Spanish expeditions. Its first settlement began with the establishment of the United States military post of Fort Brooke, during the wars with the Seminole Indians. It was the seat of small shipbuilding and salt works during the Civil War, and was captured by Federal gunboats. Its recent rapid growth dates from the coming of railroads and factories in 1886. Pop. (1910) 37,782; (1919) 52,000.

TAMPA, a bay on the west coast of Florida, an inlet of the Gulf of Mexico. The northern part is divided into an eastern arm, Hillsboro Bay, and a western arm, Old Tampa

, Lake. See DEMBIA.

GER, a family of perching birds
, allied to the finches. They are
ed by the bill being of triangular
basis and arched toward its tip. The
dible may exhibit a notched appear-
ance, are painted in moderate
feet short and slender. The hinder
ning and elongated, all the digits being
ith strong curved claws. These birds
found in the tropical parts of Amer-
clude several genera and many species,
all of brilliant coloration and usually capable of
fine singing. One of the best known is the
organist tanager (Euphonia muscina) of the West
Indies, so named from the pleasing and varied
ature of the song. The Antilles possess sev-
peculiar species. Three or four species of
the genus Pyranga are regularly
in United States in summer, one, the scarlet
tanager, or black-winged fire-tite (P. rubra),
being familiar at that season throughout all the
Northern and Eastern States and southern Can-
da. It is of less size than the robin, and a bird
of the woods and orchards rather than of open
lands, and almost never seen upon the ground.
The male is everywhere rich scarlet except his
wings and tail which are pure black. This full
plumage is not acquired, however, until the
fourth year, the young males being dull yellow,
more or less reddened according to age; while
the females are always clothed in an inconspic-
ous dress of mottled green. The song of the
male is loud, vigorous and merry, and is heard
later in the summer than the call notes of the
birds. The nest is a rather rude structure placed
in a tree, and containing greenish, brown-spotted
eggs. In the Southern States another species,
the summer redbird (P. astica) is of more pink-
sh and glowing hue than the scarlet tanager,
and lacks the black on wings and tail; it has a
Western variety (Cooperi). The males of
other Western species, the Louisiana tanager
(P. ludovicianus) are yellow and black, with the
head red; and a fourth darker species (P.
kerstingi) is mainly Mexican. Consult Ridgway,
‘Birds of North and Middle America,’ Part II,
(Washington 1902), and standard books on
American birds.

TANAGRA, tä’na-gra, Greece, an ancient
town of Boeotia, on the left bank of the Asopos,
15 miles east of Thebes, the scene of a battle
in 455 B.C., between the Athenians and the Spar-
tans, in which the latter were victorious. Tan-
gra, now called Gremada, is a scene of ruins.
Excavations since 1873 have brought many in-
teresting objects to light, especially the beautiful
vases of terra cotta draped female figures from
six to nine inches in height, known as Tanagra
figures.

TANANARIVO, tä-nä-nä-rë’vō. Capital
of the island of Madagascar. Its most promi-
ent building is the royal palace which is
located at the top of a hill. The palace has no
chapel but has a few industries and many
new buildings, among which are two cathedrals,
mosque, several colleges and hospitals and
a number of churches. Pop. about 95,000.

TANARO, tä-nä’ro, a river of Italy known
anciently as Tanarus. It rises in the Ligurian
Alps, in northwestern Italy; flows northeast
past Asti and Alessandria, and runs into the
Po 10 miles northeast of Alessandria; length
125 miles.

TANAUAN, tä-nä’wän, Philippines, (1)
Pueblo, province of Batangas, Luzon, in
the northeastern part of the province, 24
miles north of Batangas. It is on the main road
to Manila, and was wiped out by the erup-
tion of Taal in 1754, but rebuilt. It is the
centre of sugar and tobacco raising and fruit
growing country, and has large markets. There
are good schools. Pop., 20,040. (2) Pueblo
province of Leyte, in the northeastern coast, on
TANCHÉL—TANEY

San Pedro and San Pablo Bay, nine miles south of Tacloban. It is on the coast road. Pop. 18,510.

TANCHÉL, or TANQUELIN, a fanatic who arose in the Netherlands about 1115, who proclaimed himself Son of God, and had many followers. He was killed at Antwerp in 1125 and those who believed in him, known as Tanchélians, or Tanquelinians, were converted back to the Roman Catholic faith.

TANCRED, tâŋk'red, soldier and Crusader: b. about 1068; d. 5 Dec. 1112. His father was a Sicilian or Italian marquis named Odo or Ottobonus; his mother the sister of the celebrated Norman, Robert Guiscard, whose eldest son, Bohemond, was the friend and brother-in-arms of Tancrèd. (See Guiscarr.) In 1096 the two heroes embarked for Epirus, and thence marched to Macedonia. At the siege of Nicea (1097) Tancrèd first appears among the heroes who directed the course of events, and he was to play a conspicuous part in the battle of Doryleum (July 1097). He now advanced, with Godfrey's brother Baldwin, over the Taurus toward Jerusalem. Tancrèd first penetrated through the passes of the mountains, and obtained possession of Tarsus by capitulation. The perfidious conduct of Baldwin caused a quarrel between him and Tancrèd, but it terminated in the reconciliation of the chiefs, who now joined the main army which was then marching upon Antioch. On the march to Jerusalem, Tancher had command of the advance guard, and he was the first to storm the walls of the town. During the scenes of horror which attended the capture of Jerusalem (July 1099) he conducted himself with humanity. The Sultan of Egypt advanced to attempt the recovery of Jerusalem, but was totally defeated by Godfrey of Bouillon and Tancrèd before Ascalon (12 August). Tancrèd captured Tiberias, besieged Jaffa and, after the death of Godfrey, endeavored to effect the election of Bohemond as king of Jerusalem; but the unworthy Baldwin obtained the throne. Tancher subsequently conducted the defense of Antioch, and after Bohemond's death in 1111 of disease, the kingdom. He is represented by Tasso in the Jerusalem Delivered as a brilliant and blameless hero. He is also celebrated in Rossini's opera 'Tancrèd' (1813). Consult Guizot, 'Collection des Memoires-Gesta Tancrèd'; Delbarre, 'Histoire de Tancrède' (1822).

TANDOLANOS, tân-dô'lán-os, a wild Philippine tribe of Malay origin living on the west coast of Palawan, between Punta Diente and Punta Tuñuran.

TANDUBATO, tân-doo-bá-tó, Philippines, one of the smaller islands of the Tawi-Tawi group, of the Sulu Archipelago, lying off the northwest coast of the island of Tawi-Tawi; long, north and south, six miles; greatest width, five miles. The island is mountainous, Tandubato peak being the highest point. See Tawi-Tawi.

TANDY, James Napper, Irish patriot: b. 1741; d. Bordeaux, France, 1803. As a Protestant leader of the popular movement he took a leading part in American politics, free trade ascension and volunteering affairs, and was elected the first secretary to the United Irishmen of Dublin. In 1792 he went to the solicitor-general Toler, and was confined to prison till the collapse of the House of Commons. As the vicar offered a reward for his arrest, the formal action for illegality against privy-councillors, which was the final hearing. For distributing in a seditious pamphlet, he was at 12 Feb. 1793, when the government had met the Defenders and with the view of effecting a them and the United States, but crossed where he was raised to the rank of division in the French army. He fated invasion of Ireland, and landing at Rutland Island 16 Sept., escaped to Hamburg, the senate handed him over to the English on 12 Feb. 1800, he was put on trial and acquitted. He was again put up on the reasonable landing on. This time he was sentenced to new motives of policy, was permitted way to France, where he spent days. He was the hero of the song, 'The Wearing of the Green'.

TANJEPF, Serge Ivanovitch, composer: b. 1856; d. Petrograd, 20 1. He was son of a Russian gow and, while quite young, was study, forte at Moscow Conservatory. He was next sent to the public school it was decided to continue him under Nicholas Rubinstein. He under Hubert, leaving the conservatory with the award of the first gold played in Paris 1877-78, then perfo the Baltic provinces, next returni where he was appointed prof... articulation, succeeding Tchaikows... Tanganyika, tā-gān-yē'kā, central
Africa, a large lake on the boundary between
the Congo Free State and what was German
East Africa, touching its southern extrem-

ity on British Rhodesia. It lies in the Great
Rift Valley, is over 400 miles long, 30 miles
wide, and extends in a south-southeast direction
from lat. 3° 20' to 8° 44' S. The shores are
somewhat irregular but there are few islands or
reefs. The lake is hemmed in on both sides by
lofty, precipitous mountains, through a break
in which the water is discharged by the Lukuga
into the Congo, when the water is high, but in
low years there is little or no discharge.

Nearly all the surface is navigable, and sound-
ings at some points have been made to

feet. The sudden storms of the locality are,
however, a real danger to navigation. The
water is slightly brackish and swarms with
fish, crocodiles and hippopotami and some
marine mollusks, which suggests former
connection with the ocean. English and
German steamers ply on the lake; Ujiji is the
principal trading station on the shores.
The lake was discovered by Speke and Burton in
1858, and later explored by Livingstone and
Stanley. It was mapped by E. C. Hore about
1880, and the outline considerably corrected by
later explorers. The first steamship was the

Good News, launched by the London Missionary
Society in 1884, and a half dozen now ply the
waters. Consult Burton and Speke, Living-
stone and Stanley's works: Hore, E. C., 'Lake
Tanganyika' (London 1892); Moore, J. E. S.,
'The Tanganyika Problem' (London 1903);
files of the Geographical Journal, and 'Pro-
cedings of the Zoological Society' (London
1906).

TANGENT, a straight line of indefinite
length, which touches but does not cut a curve;
also the length of a straight line which touches
a curve measured from the point of tangency
to the point where it meets a diameter of the curve;
one of the trigonometrical functions. The tan-
gent to a curve is the limiting position of a
secant. Suppose a straight line as cutting a
curve in two points near to one another, and
then suppose the line to move so that the points
approach each other; at the instant when the
points coincide the line is a tangent to the
curve. Let $A B$ be any arc
less than 90°, draw $AH$ touching
the arc at $A$; from the cen-
tre $C$ draw $CBH$, cutting $AH$
in $H$; the length $AH$ is the
tangent of the arc $A B$. It is
now considered best to make a
distinction between the tangent
of an arc and the tangent of an
angle. An arc is a curved line
certain length; an angle is
not measured by the length of
arc, for the measure of a certain angle is so
many degrees, whatever may be the length in

D

Tangent.
senting the length of the other side. Consider the triangle $u$, the tangent of the angle $\alpha$.

$\tan \alpha = \frac{1}{\cos \alpha}$; this fraction is the same whatever $u$ is.

the lengths of $u$ and $\alpha$. (See Trigonometry.) A plane is said to be tangent to a curved surface when three points of the plane coincide with three points very close together on the surface. A list of the properties involving tangents may be obtained from works on analytical geometry.

TANGHIN, a poison yielded by the seeds of Cerbera (Tanghinia) venenifera, a tree of Madagascar, which is itself called tanghin. The oblong elliptic smooth leaves are crowded at the ends of the branches, whence spring also cymes of small flowers. The smooth, roundish, yellow fruits contain a fibrous nut, enclosing a poisonous kernel about the size of an almond. This kernel was used by the natives of Madagascar, to detect witchcraft, or to determine whether or not an accused person were innocent. The seed was pounded and administered to him; if it acted as an emetic, his innocence was established, and no great harm ensued; if he retained the poison he died quickly—a sufficient evidence of his guilt. It has been said, however, that the issue was arranged beforehand, and a strong emetic was given to the suspected criminal not doomed to death.

TANGIER, tân'-jër', or TANJA, tân'jâ, Morocco, a seaport town on the Atlantic Ocean, near the western entrance of the Strait of Gibraltar, southeast of Cape Spartel. It stands on a height near a spacious bay, and presents a striking appearance when approached from the sea. It is surrounded by walls, and is defended by a castle and several forts; but consists mostly of wretched houses, huddled together in narrow, dirty lanes. The residences of the European consuls, and those of a few wealthy merchants are exceptions, and the gradual introduction of good hotels, European stores, electric lighting, etc., is effecting a notable change. The principal building is the castle commanding the height, but in a very dilapidated state. The total value of the imports, chiefly from Great Britain, France (and before the war Austria and Germany), in 1914 was $4,200,000; of the exports, $2,825,000, chiefly to Spain, Great Britain, Egypt, France and the United States. The principal articles of export are eggs, oxen, slippers, wax, woolens, goat skins and carpets. The internal traffic is chiefly with Tetuan and Fez. In the time of the Roman Empire, Tangier, under the name of Timgi, was the capital of western Mauretania. It afterward came into the possession of the Vandals, Byzantines and Arabs in succession. From the last it was taken by the Portuguese in 1471, and in 1602 was annexed to the English Crown as part of the dowry of the Infanta of Portugal. In 1648 it was abandoned by the English on account of the expense necessary to keep it up. It was bombarded by the Spaniards in 1706, and by the English in 1807. Pop. estimated at 40,000 in 1911, including over 9,000 Jews, and about 10,000 Europeans.

TANGIER, a sandy island of Virginia about five miles long, in Chesapeake Bay, southeast of the mouth of the Potomac. Tangier Sound, which washes the north is noted for its large oyster beds.

TANGLEWOOD TALES, a volu
ejuvenile stories published by Hawthorne. The narrations are based on Greek and are told by a certain Fustas B., supposed narrator of the stories in H., "Wonder Book."

TANGUY, tân'ghâ, Cyprien, (clergyman and genealogist; b. O. d. 1902. He was graduated (1839) at a Seminary and ordained to the Catholic in 1843. In 1860 he founded Rimous

le and the Notre Dame Convent in Germain. He was appointed (1867) a Canadian government to make results to Canada, and in 1867, to search Europe's archives for Canadian data. He was one of the earliest Fellows of the Royal Society of Canada, He is "Dictionnaire généalogique, des famili

nadiennes" (1871-90, 7 vols.); "Le répertoire clerge canadien par ordre chronologique" (1893, 2d ed.).

TANHAY, tân-hâ, town, province cros gros oriental, on the Tanhay River, above miles inland from its mouth, 15 miles, no Dumatguete. It is near the south entra Tañon Strait, and on the coast road. 12,410.

TANIS, tân'is (Hebrew, Zoan), an Egyptian city, south of the Delta, before founding of Alexandria, the chief city of Egypt, capital of the Nekhor about 2100 B.C., and of Rameses II and neptath of the 19th dynasty, who built great temple to Set, the god of war. It is a great city for probably 2,000 years, but its prosperity was destroyed by the silting up of old Tanitic mouth of the Nile, which was from its original mouth, and it was destroyed for reb 174 A.D. The filling up of the delta has in its being left far inland, so there was no inducement to rebuild it. Numerous monuments have been made of the ruins a obelisks in all were uncovered, and many sacred temples and much statuary. It has been identified with Zoan, mentioned in her. xiii, 22, and also with Rameses. The near the fishing village on San el Hagar the south shore of the Lake of Ma'analae explored first by Mariette in 1850, and by Flinders Petrie (q.v.). Con. "Tanis" (1885); Breasted, J. H., "Anci
tords de Egypt" (1907).

TANJORE, tân-joir', India, capital of the same name, in Madras, about 45 miles from the sea, miles southwest of Madras. It is a station on the Great Southern Railway. The fortified town, about four miles in contains the palace of the rajah, paga-das and irregular streets. Outsi are other quarters, an English chu. British residences and Darjeeling, p. a tower 200 feet in height and a sull, which is one of the triumphs of art. Tanjore is an educational centre for Sanskrit literature, and has a college.

tle wrote me and said, 'I struck a
chine in Antwerp that they call a
ttractor. This machine climbs
up the slope of a hill by means of
oring a machine ever since the time of
I thought, if this tractor climbs
what we want is something that will
beat hell. At the beginning of the
peculiar position, with a knowledge
of the needs and the chance of discovering
many new things. One thing was that the
Germans had secretly armed themselves with
thousands of machine guns. The machine gun
is the most perfect man-killing gun ever made.
The Germans manufactured it in England un
under a British royalty. For a time before the
war broke out they did not pay any taxes or
submit any accounts. They knew the
war was coming and they started it with 50,000
of these guns ready. They used them like artists.
Our men went out against them and were
mowed down by thousands.

It appeared that the idea I had in July
1914 might produce a machine that would climb,
which was absolutely right. It was obvious
that launching assaults on enemy positions un
less they were first blown to dust was merely
to throw infantry into a maze of barbed wire
in which they would be caught helpless, like
flies on 'tanglefoot,' and mown down by rifle
or machine-gun fire poured in at short range
from all directions. We had to have something
to go across trenches and over barbed wire.

The machine gun was proving to be a disease
against humanity. It was invented by the late
Hiram Maxim, so you Americans have the
credit of producing that disease. But you have
the credit of producing the antidote, too — the
'caterpillar' tractor, invented by Benjamin
Holt. We started out to make that climbing
machine, the machine-gun destroyer. We made
a large number of them between August 1916
and March 1917, and kept it a secret. It
had been whispered around that they were reser
voirs to take water to our troops in Egypt.
'Reservoirs' was good camouflage, but it was a
long word, and 'tank' was better. The name
stuck. They were a surprise to the Germans.
They have taken thousands of prisoners and
have saved thousands of lives. Frederick
Palmer, the American war correspondent, esti
mated that they saved 20,000 lives on the
Somme and as many more at Cambrai, in 1917.
Not only have the tanks saved life by the moral
effect of their approach and by the number of
machine guns put out of action — but they have
themselves have taken thousands of lives."

The tanks owe their success to two essenti
first, the internal combustion engine, which
has also made feasible the use in war of the
airplane, submarine and motorized artillery, and,
second, the traction or propelling device de
veloped by Holt and established throughout the
world as a commercial success without definite
forethought as to its application in war. The
main features of this mechanism are a track
on either side of the machine, composed of a
series of steel shoes suitably linked together,
with joints protected from mud and dust; idler
pulleys for laying the shoes down in front and
driving sprockets for picking them up again
in the rear; and uprights on the inner surface of
the shoes to form continuous rail-like bands
upon which roll the truck wheels carrying the
weight of the machine. 'Caterpillar' and tank
have this much in common, that they lay down
their own rails and roll over them. Aside from
that their purpose and construction are quite
different. The tractor is a towing machine,
used in war for the rapid, certain handling of
guns and supplies, not completely armored and
not intended for trench-line duty. The war
tractor is practically a mere duplicate of those used on thousands of farms and industrial locations throughout the world. The British, Russian, French and American armies, however, adopted it as the one feasible means of moving heavy mobile artillery over difficult ground, which was not feasible in the conventional means of transport. The tractor was developed by the British and French armies, who saw the need for a machine that could carry heavy artillery and supplies over rough terrain. The tractor was designed to be simple and rugged, with a large turning radius and a high ground clearance. It was powered by a powerful engine, which allowed it to pull heavy loads over long distances. The tractor was built in large numbers, and was used extensively in all the major theatres of war during World War I. The tractor was a key factor in the Allied victory, as it allowed the Allies to maintain a strong presence on the battlefield, even in the most difficult conditions.
contains less nitrogen than dried blood: phosphoric acid. The considerable in its composition is exposed by the table, taken from Steyves's 'Soils fertilizers,' all from one factory:

See Fertil- Stock, the Feeding of.

NAHILL, tän'ah-il, Robert, Scottish ter: b. Paisley, 3 June 1774; d. there, 810. He received little education, hav- appanected to a weaver at an early wrote some of his songs while work- he made the acquaintance of Robert Archibald Smith, a Scottish, who set a number of his songs to in 1807 he published the first edition Poems and Songs; a second edition cluted by the publisher, Tannahill, re- and drowned himself. In edared a complete collection of his writ- h a memoir by Ramsay.

NER, tän'ér, Benjamin Tucker, Afri- host bishop: b. Pittsburgh, Pa., 25 5. He was educated at Avery College, y, Pa., and at Western Theological 7. He was editor of the Christian for 16 years, founded and was years editor of the A. M. E. Church and in 1888 was appointed bishop. He alegate to the third Ecumenical Meth- rinary held in London in 1801, and lished 'The Origin of the Negro' 'The Negro in Holy Writ'; 'The l Solomon — What?,' etc.

NER, Henry Ossawa, American on of B. T. Tanner (q.v.): b. Pitts- burgh, Pa., 21 June 1859. He studied under Thomas Eakins at the Pennsylvania Academy of Fine Arts subsequently removing to Paris. He became the pupil of Jean Paul Laurens and Benjamin Constant. In the Salon of 1896 he received honorable mention and a third class medal in 1897. He was awarded the Walter Lippincott Prize, Philadelphia, in 1900; Second Medal, Paris Exposition, in the same year; and medals at the Buffalo, Saint Louis and San Francisco expositions. He is rep- by paintings in the Luxembourg, the Wiltstach Collection, and at the Pennsylvania Academy of Fine Arts, Philadelphia.

TANNER, James, American lawyer and public official: b. Richmondville, N. Y., 4 April 1844. He enlisted in the 87th New York vol- uenteers and was soon promoted its corporal. Losing both legs in the second battle of Bull Run, he returned to New York, studied law, and was admitted to the bar in 1869. He re- ceived an appointment at the New York cus- ition and became deputy collector. From 1877-85 he was tax collector of Brooklyn and in 1889 was appointed United States commis- sioner of pensions, but later resigned to be- come a pension attorney. He fought tirelessly against the government 1899-1904. On 1 April 1904 he was appointed register of wills, Dis- trict of Columbia by President Roosevelt. From 1870 he was deputy-commander of the Grand Army of the Republic, New York, and 1906-06, commander-in-chief.

TANNER, John Riley, American soldier and statesman: b. Warwick County, Ind., 4 April 1844; d. Springfield, III., 23 May 1901. He enlisted in the 98th Illinois volunteers in 1863, and was with Sherman's army during its active campaign in Georgia, Tennessee and Alabama. Returning to Illinois after the war, he engaged in farming and selling fruit trees, entered politics in 1870, as Republican can- date for sheriff, was elected, and held there- after offices of circuit clerk 1872-76, State senato 1880-83, United States marshal 1883- 85, State treasurer 1886-88, assistant United States treasurer, Chicago, 1892-93 governor of Illinois 1896-1900. He was the recognized leader of the Republican party in Illinois, was the first in Illinois to speak openly for a single gold standard, declaring himself therein early 1895, and as governor his administration was able, efficient and economical. Immediately after the blowing up of the Maine in Havana Harbor, he secured the passage of resolutions in the legislature, tendering to the national government the material and moral support of Illinois in the event of war with Spain, and within 36 hours after the call for troops he had mobilized 10,000 men at Springfield, thus procuring for Illinois the honor of having the first regiment ready for muster into the na- tional service. His vigorous stand against the importation of contract labor under arms at the time of the Virden riots brought about a storm of protests that his acts were without precedent and unconstitutional. They were met with the answer that he would make pre- ceedents and construe the Constitution and the law for the welfare of the State.

TANHAUSER, tän'ho-i-zér, German min- nesinger, probably of Salzburg or Bavaria, who
TANNING

in the 13th century appears at the court of
Frederick the Warlike and other princes. He
led a monastic life and used Neidhart (q.v.)
as his model, celebrated in song the loves of the
Barbarian peasantry.

A didactic poem 'Hofzucht,' (Court Behavior)
is also attributed to him. He is credited with
the original tale of Tannhäuser the knight.

This chivalrous knight in the course of his
wanderings meets a sage named Hilario, who
instructs him in secret lore. At the same
city a lady called Lisaura conceives a violent
passion for him which he returns. Gradually,
however, the tales of his instructor regarding
spiritual beings lead him to desire association
with some beautiful spirit in mortal form.

Hilario assures him that he may attain this
at Venusberg, a hill near Freiburg, where
Venus holds her court in the midst of all de-
lights. Tannhäuser starts for the haunt of
the goddess, on hearing of which Lisaura kills
herself. For a long time the knight remains
in Venusberg, but at last his conscience touches
him, he thinks with regret of Lisaura, and
leaves Venusberg. At that time the pain of
Cain is as it is for the staff which he holds in his
hand to bud and bring forth green leaves. Despair-
ing, the knight retires and enters the Venus-
berg once more. Meanwhile the Pope's staff
has actually begun to sprout, and Urban, taking
this as a sign from God that there is still an
opportunity of pardon and salvation for the
knight, hastily sends messengers into all lands
to seek for him. But Tannhäuser is no longer
to be found, and never again appears on earth.
The Tannhäuser legend has frequently received
poetic treatment, and Richard Wagner has
adopted it (with modifications) as the subject
of one of his operas. Consult Zander, 'Die
Tannhäuser-sage und der Minnesinger Tann-
häuser;' (1880); Baring-Gould, 'Popular
Myths of the Middle Ages.'

TANNING, broadly speaking, the art of
converting the skins of animals into leather.
The skin of most of the higher animals con-
sists from the tanner's point of view of two
layers, the outer containing coloring matter,
the roots of the hair or fur, and being cellular
in structure; the inner being thicker and of
fibrous structure. The outer layer is decom-
posed much more easily than the inner by the
action of alkalis; the latter is only soluble in
water after protracted boiling, yielding a solu-
tion which gelatinizes upon cooling. Moist skin
undergoes putrefaction when exposed to the air
for some time. Dried skin is hard and brittle.

In preparing leather the object of the tanner is,
in the first place, to remove the outer layer
of the skin together with all adhering hair,
and, in the second place, to bring about such
a change in the under layer as shall prevent
it from putrefying in moist air, and at the
same time render it indifferent to moisture,
water, chemicals, etc., with the utmost sup-
pleness. The process of tanning, therefore,
divides itself into two parts. (1) Cleasning
the skin and removing the outer layer; (2) con-
verting the inner layer into leather. Techni-
cally only the second part of this process mens
the title of tanning. As supplementary to
these there is the dressing and currying the leather. The skins used by
the tanner are principally those of cattle;
the skins of horses, asses, pigs, goats, d
alligators and many other animals are
converted into leather. The quality of the
leather varies in different species of animals
in the same species, depending upon
and amount of the food consumed, and to a
still greater degree upon the vicissitudes
climate in which they are reared. Wild
cattle are said to furnish hides superior to those
domestic cattle.

In the first stage of the process, having been thoroughly washed and
of tails, shanks and pates are soaked in water
until they are sufficiently soft to allow of
adhering flesh and muscle being scraped of
means of a blunt knife; this softening proc-
gress is generally aided by beating the hides
of hammers or sticks worked by machinery.

The first is of great importance that the water be soft,
it necessary so calls upon the hides when
are green, 24 hours are allowed for the
soaking, and an equal period for a second
soaking in a fresh bath. They are use
halved lengthwise between the two soaks.
Dry hides are soaked 24 hours in water,
containing sodium sulphide, then halved and
through a dry mill for nearly an hour
then stacked up in piles for another 24 hours.
They are then put back into the same
24 hours more, again milled. Then fleshed
put into cold, clean water overnight. If
soaking is too prolonged the skin can
made into good leather. The hides are then
generally placed in pits with milk of
whereby the hair and upper layer of skin
gradually loosened. This operation requires
about six days, the hides being changed to
a fresh lime bath. They are then
subjected to the action of the dressing.
The final process preparatory to tanning
sists in hating the hides in a very dilute
liquid in which a mild putrefactive ac-
tion is going on. This bath is made with lactic acid and glucose, the
furnishing the fermentative ingredient.
Hides, which continues for six days, the
is entirely removed and the hides are
considerably softened and swollen. The
pared hides may now be tanned — that is
able to withstand putrefaction without
of suppleness — by the action of diffe-
materials. These materials may be two
ited as (1) tannin, (2) metallic salts
 oily matters. When tannin is used it
always called tanning. When metal
are used the process is in some
socalled tawing; and when oily matters are
shamming or oil-tawing.

Vegetable Tanning.— The sources of
in used in the vegetable tanning proc-
chiefly oak bark and hemlock bark. The
is taken from the yellow and red oak,
all oaks carry a proportion of tannin, which may be available for this purpose.
The tannin content of the best oak bark
from 9 to 14 per cent. Hemlock bark is
much larger supply, and, therefore, is more
largely used. It carries from 7 to 8 per cent.
gradually increasing strength. The tannin is thus caused to penetrate the hides completely. The thinner hides must be immersed for 6 or 8 weeks, the thicker for 12 or 24 weeks in the tanning liquor. A more rapid process is obtained by combining the tanning agents. A liquor compound with quebracho extract and palmetto extract is one of the quickest, and the leather may be pressed and split and the grains retained after 18 to 20 days. The modern tanner divides his work into three stages: in the first the hides are colored by immersion for 24 hours in a weak liquor, activated by one part of hemlock to two parts of quebracho; in the second stage the tanning process is carried forward by strengthening the liquor by fresh additions twice daily until it tests 30° (barometer); the third stage follows the pressing to remove superfluous liquor and the splitting of the hide into grains, and is a retanning process with a strong gambier and sumac liquor; for about one hour. The entire process may be completed within eight days.

Mineral Tanning.—This process depends upon the action of chromic acid instead of tannic acid. Of very recent introduction the chrome process has extensively displaced the much slower tannic acid processes and its product seems equally durable and acceptable in the industries. After the hides are bated and washed they are pickled with sulphuric acid and salt or with aluminum sulphate and salt. They are then put into a solution of salt in a vat with paddles, and the paddles run for half an hour. The chrome liquor, a compound of potassium bichromate and sulphuric or muriatic acid, is then added until the bath reaches 50° B., the paddles running for one hour. More of the chrome liquor is then added, and the paddles run for three hours longer. The remainder of the chrome is then added and the hides left until the tanning is complete, which will take about six hours. They are left in the liquor for 12 hours longer and then pressed and placed in a second bath of sulphurous acid and finally washed with a solution of salt, when they are ready for splitting and retanning with gambier or palmetto. This is the process commonly employed in making calfskin, goatskin and sheepskin leathers, though they are often tanned with alum. In the latter case, when the skins have been washed and prepared by being submitted to processes closely resembling those already described they are separately soaked in a tepid bath containing alum and common salt dissolved in water; they are then, without being dried, placed in heaps for a few days, after which they are wrung out and dried slowly by exposure to air. The alum bath for 10 skins is usually prepared by dissolving 0.70 kilos of alum and 0.30 kilos of common salt in 22.5 litres of boiling water. Aluminium chloride is produced by the action of the salt and alum, and is absorbed largely by the skins; the excess of salt appears also to aid in the conversion of the skins into leather. The tawed and dried skins are softened by being dampened and stretched between a curved iron and a movable steel plate, after which they are again dried. Heavy hides are sometimes tawed for the use of the saddler by steeping them in a bath containing a larger
TANNINS

quantities of alum and salt than that mentioned above, drying them and then rubbing them with tallow before a charcoal fire. A very strong leather may thus be prepared in a comparatively short time. The more delicate kinds of leathers, however, require that for making kid, gloves, kid shoes, etc., be tawed by immersion in a bath containing alum, salt, yolk of eggs, wheaten flour, and water. The oil contained in the egg yolks confers upon the leather a great degree of softness, the gluten of the flour seems to aid the skin in the absorption of aluminochloride. The skins are stretched by hand and rapidly dried in the open air; they are then damped, placed between linen cloths and trodden upon until they become soft. They are finally polished by rubbing with a glass disc smeared with white of egg or a solution of gum, etc.

Oil Tawing.—So-called wash leather or chamois leather is prepared from the skins of deer, sheep, calves, etc., by tawing them with oil. The skins having been washed, limed, etc., in the ordinary way, are repeatedly rubbed with animal oil, exposed to the beaters of a fulling machine, and dried. The oil employed is turpentine oil. It is believed to replace castor oil with sulphuric acid. Other oils have been employed, but castor oil remains the only oil which has been successfully sulphonated. A small quantity of carbolic acid is sometimes added. The skins are stretched and sprinkled with oil, which is gently rubbed in with the hand; they are then placed in bundles in the fulling machine and exposed to the action of the beaters for several hours. After exposure to the air the skins are again rubbed with oil and again placed under the beaters; these processes are repeated until the fleshy odor of the original skin is no longer perceptible. By exposure to a warm atmosphere a process of gentle fermentation is originated within the skins, whereby the pores are dilated and the oil is enabled to penetrate the mass more thoroughly. The excess of oil is finally removed by washing with a dilute warm caustic lye; the skins are then dried and dressed. Wash-leather is much used for making military belts, gloves, socks, etc., for surgical bandages, stuffed chair coverings, and for polishing jewelry. A great variety of other processes are in use for tanning, many of them being patented. These formulas call for such ingredients as witch hazel, horse chestnut, poke-root, cranberry, blackberry roots, persimmon bark, licorice, fornic aldehyde, sodium nitrate, chromium chloride, iron sulphate, zinc sulphate, etc. For specific purposes these may have other uses, but the basic processes of tanning have remained unchanged for many years.

The manner in which tanning is conducted in different establishments varies much in detail, although the general principles are the same. In some of the older processes, which might be expected from ancient knowledge, each tanner treasures his secret as to the best process for bringing about the desired modification of which it is competent to speak. And these secret methods, the value of which can be proved by skillful experience, is inevitably overestimated by those whose knowledge is confined to that experience, prevent comparison and the rejection of superfluous and perhaps injurious operations. The trade of tanning may, however, be still in its infancy, and it must be that the chemical processes involved has been solved. It was only at the 18th century that scientific methods were applied to leather-making, and a much progress has hitherto been considerable activity has been shown in the improvement. The extreme slowness of leather-making by any of the ordinary processes of tanning has afforded motive for inquiry as to whether hastening it by additional contrivances has been saved by splitting the as it comes from the lime pits, and tannin thinner splits individually. The neces:

preserving the solidity and tenacity of hides seems to militate against any method of progress in the passage of tanning agents through and through them.

TANNINS, or TANNIC ACIDS, are pound of high molecular weight, wide distributed in the vegetable kingdom. Some of are found in diseased vegetable tis in abnormal growths, while others are in the different parts of the healthy Gallotannic acid is present in gall-nut, tannic acid in coffee beans, tannin in yellow wood, quercetin acid in oak ellagitannic acid in pomegranate. These tannins are not by any means in all their physical properties and their conduct; still they possess some char acties in common. They are usually amo have an astringent taste, dissolve in hot convert animal hide into leather and yield blue or green precipitates with ferric sa these varieties gallotannic — the chi stitution of the commercial product — ha any other tannin, received the att of investigators. The statements in this refer chiefly to this compound.

Gallotannic acid is extracted from po calls by treatment with aqueous or al alcohol. On standing the mother liquor an upper layer containing gallic acid other impurities and into a lower layer which crude tannic acid is obtained by tannin evaporation. From this produ impurities may be further removed by tre with dry ether in which the acid is int ethyl acetate and acetone have also bee quite extensively for the extraction and preparation of tannic acid. The compou further been purified by treating its
or suspension with lead acetate. This precipitate a lead salt which is readily used with hydrogen sulphide.

This precipitate is a substance with astrignent taste, soluble in water, or alcohol, glycerine, ethyl acetate and almost insoluble in dry ether, chlorophene, carbon bisulphide and petroleum.

Its aqueous solution gives an acid with litmus, although its acidity cannot be determined by direct titration, an indication practically valueless. With pure salts aqueous solutions of tannic acid coloration at first, but a color is soon developed by atmospheric oxidation and a blue-recipitate is ultimately formed. With salts a bluish-black precipitate is at once produced; this reaction is taken as the basis for the estimation of the compound in the preparation of ink inks. Cold alkaline solutions of acid absorb atmospheric oxygen very slowly in forming highly-colored oxidation products. A similar acid solution forms precipitates with metallic salts, with a number of acids, with nearly all alkaloids and their salts, albumin, gelatin, starch, and gelatin, albumin, and starch. A solution of the acid is converted into leather. At 215° C. the acid decomposes into water, carbon dioxide, and metagallic acid and dinitro dihydric acid. It is hydrolyzed by gallic acid.

Anic acid is extensively employed in the manufacture of gallic acid, in the preparation of ink dyes and in dyeing. With formaldehyde forms a condensation product which in the manufacture of hygienic fabrics and acid has found extensive application in medicine. It is recommended as an anti-metabolic poison with which it usually nontoxic precipitates. It is employed as a mordant to prevent excessive secretion in sores and to check bleeding. Tannin (tannyl triacetate), tannic acid (gelatin), tannin and bismuth tannate have been employed in intestinal caustic. Tannic acid is also used in tannin, and in the treatment of skin diseases, tannin in the treatment of scalp diseases.

though oak-bark, gall-nuts and other sources of tannic acid had been used incidentally, the compound was first isolated by Scheele in 1787. Benzilifer assigned to it the formula C${}_4$H${}_8$O${}_6$. (1834) modified this to C${}_4$H${}_8$O${}_4$. In olden called attention to the hydrolysis of acid into gallic acid. Siemen believed that this acid was a glucoside, which three molecules of gallic acid existed with one molecule of glucose; while up to the present day have contended that purified substance contains no sugar. Schiff claimed to have converted gallic acid into tannic acid by a process of condensation called his product digallic acid and its use in the formula C${}_4$H${}_8$O${}_6$, which had been adopted by some earlier investigators. Digitalis extract has been used for many years, but in 1890 Ph. van Nist, C. Scheible and others made the discovery that tannic acid was optically active, and that rendered Schiff's digallic acid form improbable. After several years of study Nierstein (1908) announced the conviction that tannic acid was a mixture of Schiff's digallic acid and optimum tannin. While Emil Fischer's researches with the carefully purified substance pointed to the conclusion that tannic acid might be considered as a compound of one molecule of glucose with 10 molecules of gallic acid. The hydrolysis of the compound into glucose and gallic acid, as well as its synthesis, are cited as possible confirmations of this view. At the same time it is frankly admitted that the question of structure has not received its final settlement.

Of late years compounds showing the properties of tannic acid have been prepared by synthetic processes. Of these so-called *Syns.-tanis,* Neradol and Neradol D deserve mention. They are obtained by heating phenol sulfonic acids with formaldehyde. It is claimed that the amount of Neradol required to treat skin is less than that of any vegetable tannin.

TANOAN, t'a-no-an, or TAHANO, FAMILY, a linguistic stock of American Indians inhabiting a group of pueblos in the Rio Grande Valley, New Mexico. The chief of the modern villages are Isleta, Jemez, Picuris, Pojoaque, San Ildefonso, San Juan, Sandia, Santa Clara and Taos. They are considered the most representative pueblo group, and are probably the most ancient of the pueblo settlements. The villagers who number about 3,000 have not perceptibly advanced in civilization, from the descriptions given of them by Spanish explorers who first visited the villages over three centuries ago. Deriving their name from Tahano, the Indian name of the chief Tano pueblo, they then inhabited a number of other villages, now in ruins, in Mexico, Texas and Arizona grouped under the names Tano, Tewa, Tigua and Piro. Consult Bandelier, H. F. A., 'The Indians of the Southwestern United States, 1880-91' (Boston 1890-92).

TA'NON, tâ-nôn', a strait in the Philippine Islands between Cebu on the east and Negros on the west; the northern entrance is 20 miles wide and the southern entrance five miles; the length is 103 miles. The shores are steep and generally free from obstructions; there are a number of important towns on its coasts.

TANREC, or TENREC, a genus (Centetes) of insectivorous mammals, distinguished by the elongated muzzle and the short rounded ears. The body is covered on the upper surface with spines and bristles; no tail exists. These animals inhabit Madagascar, the most familiar species being the centetes ecaudatus, while other species are the tendrac or spiny tanrec (C. spinosus) and the banded tanrec (C. madagascariensis). The C. ecaudatus is an animal of about the size of the European hedgehog, but with a larger body, the legs being also more elongated. The quills or spines are yellowish at their bases and black toward the tips. These animals hibernate like the European hedgehogs and live in burrows, which they excavate by means of their strong claws. They do not, however, possess the power of rolling themselves up into a ball-like form for defense. The food consists of insects, rep-
TANSY, a composite herb (Tanacetum vulgare), introduced into America from the northern Old World. It is a familiar weed of waste lands and roadsides, probably escaped from old herb gardens and maintaining its position with vigor—a characteristic which is said to have suggested the Greek name Athanasia, "immortality," which has been corrupted into "tansy." It is a handsome plant, with dark-green, deeply cleft and pinnaed, fern-like leaves, numerous on an erect stem about three feet high, which is topped by something dense of round flat, button-like, gold-colored heads of rayless florets. It has a rank odor and bitter, aromatic flavor, which caused it to be used formerly as a seasoning herb, a practice now practically obsolete. The acid juice contains a volatile oil that is very poisonous, yet tansy was a popular anthelmintic and stomachic drug and still holds a place in materia medica as an aromatic, bitters and irritable narcotic; it is employed to relieve the pain of ulcers, bruises and rheumatism. White tansy is the sneezewort, and several other plants of similar aspect are also called tansy; while Argentiniana anserina is the goose-tansy.

TANTA, or TANTAH, ðn-tä, Egypt, capital of the province of Gharibeh, in the Delta, about 55 miles by rail north of Cairo. It has large public buildings, a palace of the Khedive, bazaars and three important annual fairs. The centre of education is the Mosque of El Ahmadi where in 1914 2,860 students and 113 professors were registered. Pop. about 59,000.

TANTALITE. A rare mineral consisting of tantalum of iron and manganese, with 72.4 per cent of tantalum when pure. An important source of that metal, at one time used extensively for filaments for incandescent electric lamps; obtained in Black Hills of South Dakota and in Virginia.

TANTALUM, chemical symbol Ta, atomic weight 183, is a rare element found by Ekeberg (1863) in a mineral afterward called tantalite (Pillowite) obtained from Finland. It is also found in the minerals sarsamkite, yttrotantalite and fergusonite. The other rare element columbium is usually found with it. The metal is obtained by heating the potassium and tantalum hydroxides with metallic potassium and extracting the potassium fluoride with water. It is a black substance with a metallic lustre, insoluble in sulfuric, hydrochloric or nitric acids or aqua regia, but soluble in hydrofluoric acid. Like columbium it ignites when heated in the air, forming tantalum oxide, Ta₂O. This oxide unites with certain metallic oxides or hydroxides to form compounds called tantalates which may be considered as derived from hypothetical acids called tantalic acids. Tantalum is used in the manufacture of electric lamps. It is found in pegmatite veins in the Black Hills of South Dakota and at other places in the United States. The chief supply comes from Australia and Scandinavia.

TANTALUS, ðn-tä-läs, in Greek mythology, king of Lydia; son of Zeus or Tmolus. Tradition does not agree as to the crime by which he forfeited the favor of Zeus and merited confign punishment. According to one account he offended Zeus by his perjury; according to another he stole away the nectar and ambrosia from heaven, and a third story is that he murdered his own son Pelops and served him up as some of the gods. Homer represents him as standing up to his throat in water, with the most delicious fruits hanging over his head, which, when he attempts to quench his thirst or to appease his hunger, elude his grasp. According to Pindar a great rock is suspended over his head, which constantly threatens to fall and crush him.

TANTIA TOPI, tân-tēâ tōpē ("the weaver who became an artilleryman"): h. Bithur, near Cawnpore, India, about 1819; d. 18 April 1859. Rebel leader during the Indian Mutiny of 1857. He displayed marked ability, beginning as a lieutenant of Nana Sahib, after the flight of the latter into Nepal, he assumed command and continued the war for months, putting the English to no end of trouble, being the last rebel, with his entire army, to be captured, tried and hanged in April 1859.

TANTRA, the name given in Hindu religious lore, to dialogues between the god Siva and his bride in one of her many forms, but chiefly as Uma and Parvati. The Tantriks or followers of the Tantras, consider them a fifth Veda and attribute to them equal antiquity and superior authority. In them is found instruction in the methods of acquiring six superior faculties, as what would now be termed clairvoyance, second sight, observation on the astral plane, viewing the body, etc. Meditation and its results is dealt with at great length, breathing instructions are given that suggest modern Yoga practice and there is instruction in the languages of animals Consult "The Tantra of the Great Liberator" (trans. London 1913). See INDIA.

TANTUM ERGO, tän-tüm er-go, the hymn sung in the Roman Catholic Church at benediction with the Holy Sacrament.

TANZIMAT. See TURKEY, GOVERNMENT.

TAO TE KING. Laotze, author of the "Taô Te King," "Book of the Way and Virtue," lived in the 6th century B.C, and was keeper of the archives at the capital where Kongtse (Confucius) visited him. Later many legends, borrowed from Buddhism, gathered around his memory, until he became chief deity of the Taoists and his "Taô Te King," their chief scripture. (See Taoism). The "Taô Te King" treats the world, man, morality and politics in reference to Tao, variously translated Way, Word, Reason, Nature, God. An understanding of the "Taô Te King" is greatly aided by familiarity with Brahmanic and other mysticism; and Douglas even supposes that Laotze derived his doctrines from India; but if so he thoroughly assimilated it to the Chinese mind, while his references to Chinese antiquity indicate originality. In any case, Tao is distinguished from the ontological Brahma by the characteristic Chinese stress upon its ethical content, Tao is the Absolute which unfolds its mysterious nature into Shang-ti (the Chinese personal god), the rational world, and moral man; and it may draw all three again into itself. After introducing his Tao, Laotze passes from one theme
er without logical sequence, but always
to exemplify the working of Tao, as usual with the Chinese, to the moral
tical spheres. Laotze was no philosopher;
but, like his great rival, Kung-tse, was
a remedy for the troublous times in
he lived. Laotze's remedy was a re-
Arcadian simplicity, such as existed be-
less and laws were devised or needed.
ismissimistic rejection of entire human
Laotze constantly joined rejection of
features, such as ambition, pride,
y and greed; while he commends its
weak but indispensable elements.

others, the more does he have himself.
Legge. I. The 'Teachings of Taoism' (2
Sacred Books of the East').
EDMUND BUCKLEY.

TAOISM. Taoism ranks with Confucian-
Buddhism as the three great religions
a, which amount in practice to one re-
compound, wherein Confucianism is
oral and ceremonial. Taoism is re-
and magical, while Buddhism deals in
chosis and the future life. Only the
are exclusive followers of either Taoism
hism. There are even 'temples of the
ines', where idols of Buddha and
and stand on either side of Kongtze. The
ask about a religion not, 'Is it true?'
it moral?'. Tested thus, all their re-
seem to the Chinese acceptable.
ism is the folklore of the Chinese,
but having received various accretions
the centuries, such as a corrupted form
ze's doctrine of the Tao (from which
takes its name) in the 6th century B.C.,
defined as Yu Hwang in the 7th A.D. and
Kwan-tze, both of whom are defined as
d only in 1828. Especially in the three
5 B.C., emperors and folk alike, under
ership of Taoist priests, neglected labor
for the elixir of life and for power
bility become gold. Thus
cluded to include most of the national
hero-worship and nature-worship (of a type
lower than Confucianism) and most of the
divination and magic, the latter including
fengshui, the Chinese geomancy, according
to which the location of a house or a grave de-
deps on supposed magnetic currents; the azure
dragon, the white tiger and the like. This folly
strong enough to form the chief obstacle to
civil engineering in China, as when a telegraph
pole would disturb the fengshui of a region or
a railway that of a century!
The gods of Taoism furnish a good index
to its heterogeneous origin. The San Ching,
"Three Pure Ones," are simply a tripllication
of Laotze, done to correspond with a Buddhist
triplet. But, since these are sunk in contempla-
tion, the superintendence of mundane affairs
falls to Yu Hwang Shang Ti, "Gemmous
Sovereign God." The first elements have souls
which rose to become the five planets and thus
divine. Many stars are defined. The Dragon-
kong, a familiar feature of Chinese processions,
seen even in America, represents water in its
varied forms and, therefore, has numerous
temples besides seas and rivers and is discerned
among rain clouds. Sun cult survives in the
bonfires of the spring festival. Licentious fes-
tivals were long ago suppressed in accord with
the politico-ethical nature of the dominant Con-
ufucianism. Sacred animals are the fox, snake,
edgehog and weasel; sacred trees are the cas-
sia, willow, banyan, pine and peach. To the
ancestral tablets and an image or picture of the
Kitchen-god (originally a Fire-god) found in
every Chinese house the Taoist adds certain
other figures according to locality, trade and
preference.
Taoist worship also certain culture-gods
who preside over various vocations. Thus,
students revere Wan-chang (a deified scholar)
as God of Letters, soldiers worship a deified
soldier as Kwanti the God of War and traders
people worship Tsai-Shin, God of Riches. Be-
sides such great gods there are innumerable
"spirits," of whom Chinese live in dread by
day and especially night.

The priests of Taoism are probably cognate
with the shaman of Siberia, but its monks,
nuns, pope, monasteries and temples were
copied from Buddhism. These priests conduct
the ritual for the city and State gods, for
fty streets, houses and persons from evil spirits,
and prepare paper amulets for pasting on door-
ways to exclude spirits. Though Taoist priests
marry, their vocation is not hereditary, they are
recruited from the lowest classes, are ignorant
and immoral, and are generally despised by the
"literati", the learned officials of China. From
these priest-magicians one must distinguish the
monks who observe Laotze's principles by
 celibacy, seclusion and mystical communing.

The Taoist scripture is far less the recondite
'Tao Te King' (q.v.) of Laotze than "The
Tractate of Actions and their Retributions," an
anonymous tract composed about the 11th cen-
tury A.D., which is universally popular. Its 212
brief statements fall under five headings, the
first of these declares that happiness follows
virtue as misery follows vice; the second states
that "spirits in heaven and earth," in "the great
Bear constellation" and within "men's person"
vortices man must practice and their reward in
making him an "immortal"; the fourth, and by
far the longest, names the vices he must shun;
while the fifth provides for repentance and
enacts a new rule of theology. The tract is
characteristically Chinese, agreeing with Con-
fucianism in its stress upon morality and in its
belief in an earthly theology; but its doctrine of
the Buddhist pantheon, as developed in a Bud-
dhist. Another popular religious tract, the
"Book of Secret Blessings," expresses in 541
words brief moral rules with a flavor equally of
Taoism, Confucianism and Buddhism, by all
of which indeed it is approved.

In centuries Taoism further adopted from Bud-
dhism its doctrine of hells and it exhibits in its
temples realistic figures of the damned under
torture. Foreigners name such a temple
"Chamber of Horrors," and its gruesome
spectacles are well adapted to terrorize the ob-
tuse minds of the Chinese masses.

Books of the East."

EDMUND BUCKLEY.

TAPAJOS, tâ-pâ-zhôs, Brazil, a tributary of
the Amazon, formed by the confluence of the
Arimas and Jurunena, which rise on the edge of
the Brazilian plateau in the state of Mato
Grosso. The main stream is at first hemmed in
by mountains and obstructed at intervals by
rapids, but after it enters the state of Para it
is a broad and deep stream. It enters the
Amazon at Santarem in about long 54° 20' W.
A few miles above its mouth it broadens into a
lake-like expansion 12 miles wide and 75 miles
long. The river is 1,040 miles long and steam-
ers ply on it for 210 miles.

TAPESTRIES. The peristromata of the
ancient Babylonians were highly praised by
Homer, Hesiod, Thucydides, Strabo, and,
Palaces and temples of the 13th and 12th
centuries were covered with tapestry hangings;
the houses of the 12th century, were of embroidery work,
not woven. The walls of many European Con-
tempar churches and princely palaces were
covered with rich warp 
kaute (fr. tapestry) hangings by the 14th century. The terry-
lookers are used as the walls of halls in manors of the 14th century from which the
pictures were suspended. Certain tapestry hangings are still in the remains of the Arcadian
Empire (Eapom) which are
our ancestors in our modern sense of the
word. The history of their production is
very obscure. The term called "tapest-
ries" develops from different periods through
the 7th, 8th, 9th, 10th, 11th, and 12th centuries and have always been worked in the form
of pattern work, attached to clothing as a border
decoration. These very ancient pieces display
fluorous decorative designs in several colors.

Gothic Tapestries. By the 14th century, incited by the Oriental works of art brought
back by the returning Crusaders, Europe
started an era of industrial art work. Flanders
progressed most rapidly in the art of weaving
tapestries and her "imagery cloth" (drap
imagéz) produced formerly became famous; so much so that the term "arras"
soon became the familiar name for tapestry
and still remains so in some languages. Brus-
ells became the next centre of this industry to
be followed by Bruges and Flanders. From the
last half of the 15th century to the middle of
the 16th century the richness and pure beauty of the "Gothic" weavings produced
have caused the period to be termed the Golden
Age of tapestries; it is frequently referred to
as the "Gothic Renaissance." Arras and Paris
were now vying with each other as the
principal centres of production. Every royal court
and every baron and knight showed en-
thusiasm in acquiring fine tapestry hangings
and to pride the halls of their castles and
palaces. The tapestries produced from 1483 to 1515 are generally considered
by connoisseurs as the greatest achievements of
the weavers' looms known from the point of
pure art. But these beautiful hangings were
not confined to the castles of royalty and nobility, for the wealth merchants acquired
them and displayed them from windows and
balkonies for the admiration of the passing
world. At the time the streets were decorated for various occasions, honor of royal and civic processions and fests.
The lists, at tournaments, were gay with such
tool rich decorations. With the advance of time
we find primitive stiffness in depiction, entailed
with the Byzantine influence and ecclesiastical demands, gradually pass to the soft curves of
naturalistic expression. The great space, for-
merly divided up into numerous scenes by
quaint separating motifs of Gothic columns and
arches, now becomes one of scenes blending
into one another, later to be given over to one
main scenic picture. The backgrounds in the
early Gothic weaves were occupied by
dense masses of plant life (an Oriental decora-
tive method, doubtless acquired through the
Crusades) and known to us as "verderas" pass
to landscapes and castles lacking in perspec-
tive. These verderas are known to the au-
tormer and his catalogue as "mille-fleurs" or
account of the many little blossoms peeping
out from the branches. Another style was called "a personnages" crowd in the
background with persons streaming from
hills, churches, palaces. Belonging to this early
period of unmodified art we find such talanted
artists as Nicolas (or Colin) Bataille, the
Parisian. In the 14th century France and Flanders: Jacques Dourdin, who worked under the Duke of Burgundy.
tapestry designer was Jan van Room de Rome) in a Gothic-Renaissance style. Figure-decorated pieces are known as

riatted. The decadence of the tapestries sets in with the 16th century; the now attempts to imitate the painted can-

weave in wool to simulate brush workments. To get this strictly artificial effect w simple woolen dyes have to be multi-

into innumerable hundreds of color tones shades. The genius of a Raphael is called slay to design (1513) the "Acts of the es" set of cartoons for tapestries to the Sistine Chapel at Rome. In about 1517, Peter van Aelst, at Brussels, had luced the great work into color in the "They cost Pope Leo over $130,000, in

of that date. This ended the purd of tapestry treatment in the Flemish s and Renaissance painting in wool takes use of Gothic, for the weavers of Brussels ther northern centers now got cartoons from the Paris Cathedral of Notre Dame, Andrea del Giulio Romano and other Italian artists ow out on their looms. The "Acts of the es" designs were later reproduced in European centres. Wilhelm de Fanne-

was noted for his work in this period tyle, as were the Pannemaker family. The enormously increased demand the s grew vastly in numbers and we have s in Brussels, Arras, Tournai, Bruges, en. Oudenarde, Middlebourg, Lille, Ant-

and Delft. As might be expected with a ug demand much greater than the supply, and deterioration set in from careless ion. Low warp (basse lises) were l Rubens was making cartoons for the lands now.

lian Tapestry Factories.—Already in ohannes Thomae de Francia (French) managing, at Mantua, an atelier for the ga family. Succeeding him came Nicolai, te, Adamante (all French). And Flemings employed about 1450 (Rinaldo Boterm of Is, and one Rubichetto). Giovanni del fì and Andre Mantegna did cartoons. nice looms were started by John of i. talfalda and also by Andre Mantegna. m set up looms also in Siena. Renault incourt (about 1455) did "The Creation World" for Pope Nicholas V. In 1441 a had looms worked by the Flemings di Andrea and Giacomo de Angelo; Nicolai and John Racker worked there. Lucas Cornelisz the designer. Rost and ther Flemings arrived, a school was i and a local artist, Battista Dosso, de-

"Life of Hercules," "Scenes from orphs" for other beautiful work. pieces of this school are (in Ferrara ral) "Story of Saint George and Saint lius" and (in Como Cathedral) "Story Virgin." In Florence the Medici estab-

lished an atelier called "Artezzaria Medicea 1737), under Karcher and later Johan Stralen was director about 1570 and olific work. Many pieces are in the ce Tapestry Museum, including the Kar-

ad Rost best productions "The Story of s 1700" and "The Cartoons designed opo Sansovino, Bacchiacca and others. weavers (17th century) were Papini, Van Asselt, Lefèvre, Pollastreri, the two Tumini, Van Bartoli, Manzi, Cavalieri, Buonaroti, Rome, Cardinal Barbarini (1633) established an atelier with Jean François Romanelli as art director, Giacomo della Riviera director of works, M. Wauters (of Flanders) was a creator. "Scenes from the Life of Christ," in 11 pieces, in the Cathedral of Saint John the Divine, New York, are from this factory. In the Hospitale Saint Michele, Rome, Pope Clement XI started (1710) an atelier with Jean Simonet of Paris manager, and A. Procacci art director. Perioli was manager from 1717 to 1770. In Naples (1737), the Florence Medici factory having closed, its weavers started here and ran till 1799. Under Benedetto da Milano the Vignevo works started (16th century) and produced the "Trieste Months" for Marshal Triuise, now in this family's Milan palace.

German Factories.—Otto-Heinrich had an atelier at Launing in the 16th century. Peter Candid designed and Hans van de Biest wove (17th century) "The Four Seasons" and "Day and "Night" six pieces for the Museum in Munich.

French Factories.—François Premier, after his Italian campaign, started an atelier (about 1535) at Fontainebleau. The "History of Diana," was done in honor of Diana of Poi-

liers. Under his son (Henri III) it became de-

 funct; but (1551) Henri opened an atelier at the orphan asylum, La Trinité, employing the children on the work. The "History of Manosolus and Artemisia" (15 pieces) were made here by Maurice du Bourg, its chief, from the designs of Larembert and Caron. Other factories have reproduced it. Henri IV started both high and low warp looms in 1597 in faubourg Saint Antoine ateliers, under du Bourg and Daurent; and, about 1601, Flemish artisans were invited to Paris. Frans van den Planken came from Oudenarde and Marc de Coomans from Brussels and started an atelier in Paris with branches in Tours and Amiens. Henri IV decided to accelerate the industry still more by installing du Bourg and Laube in the Louvre and de la Planche (van den Planken) with Coomans in Les Tournelles palace. The latter works was moved to faubourg Saint Marceau, Paris. Louis XIV patronized the industry. Piere Lefèvre and his son Jean (Florence weavers) came to Paris in 1647. The high warp looms of Tours got Cardinal Richelieu's patronage. Rheims, under direction of Daniel Peppersack, produced "The Story of Christ" and other works. Fouquet of Vaux-le-Ménil started an atelier (1658) on his estate and Le Brun drew cartoons for it ("The Hunt of Meleager"); Louis Blammaert directed the Flemish weavers. When Fouquet, as successor of Mazarin, fell in disgrace, the Maincy factory was closed, after only three years operation.

Beauvais Tapestry. —Minister Colbert (1664) persuaded Louis Hinet, owner of Flanders ateliers, to move his looms to Beauvais under such attractions as a subsidy, the presence of Court orders, and 30 years' a-

college. Hinet was bankrupt by 1684 and was succeeded by Philipe Behagle, who started making full-sized figure pieces. High and low warp looms were operated, but the large pieces showed very little demand. Behagle started a school of design under management of M. Pape and many of the small pieces (low warp),
of great beauty, for furniture, came from designs of this class. On Behagel's death his sons failed and the brothers Filleul took over the business only to fail likewise. In 1722 the atelier was run by Sieur de Mérou, who engaged Jean-Baptiste Oudry (from the Gobelins). Oudry's genius in designing cartoons and management made Beauvais noted. Perfect workmanship marks this period; verdures are delightful, cute ducks, pheasants, foxes, dogs, are featured. Charles Natoire (from the Gobelins) used his talent on furniture. Mérou's financial losses brought Nicholas Benisier as successor. Noted designers of Beauvais pieces are François Boucher, Leprince, Casanova, etc. Low warp pieces predominate. Benisier's death in 1753, followed by the death of Oudry two years later, injured art values of future Beauvais pieces although, under the auspices of André-Charlemagne Charron (1753-1780), the factory was quite a success. From 1780 Sieur de Mérou (from Aubusson) was director, and introduced the use of napier and tapestry weave. The Revolution injured the industry and for one year it was closed but the factory has been kept running ever since. Among extant Beauvais pieces are "Conquests of the East" (two pieces only) in Florence; Raphael's "Acts of the Apostles" (eight pieces), one set in Beauvais Cathedral, another in the French National Collection; "Adventures of Telemachus" (six pieces) in the Royal Spanish Collection, several in Paris; "Bibles du Château" of Sweden (four pieces) in the Royal Swedish Collection. Oudry's "Fables de La Fontaine" designs for chairs gained great popularity and were reproduced prolifically. In the archbishop's palace at Aix-en-Provence are a set of Natoire's "Don Quixote" (10 pieces). Quite a large number of Boucher's pieces are in the United States.

**Aubusson Tapestry.**—The origin of this factory is in doubt, but the Duches of Valentinois' will (dated 1507) mentions the "tapissiers de Feltelin" and Feltelin is a town near Aubusson. Henry IV (late 16th century) lent the Feltelin and Aubusson ateliers assistance by forbidding Flemish tapestry imports. Savary's "Dictionnaire du Commerce" (1641) says: "There are also two other French tapestry factories, one at Aubusson in Auvergne, and the other at Feltelin in La Marche." In 1637 Aubusson had about 2,000 operatives, but both material and designs were of a low order as well as the dyes, and weavers were leaving. Colbert promised a talented artist and an expert dyer. But they never came. The king permitted the use of the title "Royal Manufacture" and promised a good painter, who did not appear. Financial conditions at the Court were bad. However, the factory continued. But in 1685 the revocation of the Edict of Nantes set the best weavers in flight, for they were Protestants, much to the injury of the factory. Louis XV in 1731 sent the efficient dyer (Sieur Fizameau from the Gobelins) and the promised painter (Jean-Joseph Dumons). Dumons' designs were a success. Fizameau was succeeded by Jean-Philippe Montenier. An ordinance of 1732 enforced the weaving of the initials of the town and weaver into the blue border. The Revolution closed the factory, but ever since it has been running with success. Aubusson looms are all low warp. The product is furniture tapestry.

**Savonnerie Tapestry.**—The textile produced at this factory is not what is known generally under the name of tapestry because it has a very different material which originated in the East and had been called "tongue laine" (long wool) or "la façon Perse," also after the fashion of the Persians. Pierre Dupont and Simon Lourdert started for this work in 1657 in the Louvre with a license to weave carpets in the style of Oriental, with gold and silver. The plant moved in 1631 to the old soap works (bourdonnerie) at Châtillon. Louis XIV purchased (1712) the works to assume the title of savonnerie royale des Meubles de la Cour des Tapis façon de Perser et du Le. They gained the same privileges as the Gobelins. The king and his successors, L.VI, VII, VIII, patronized the industry and gave it extensive orders. While the process was knotted work cut to pile, it has ever been as tapestry. Much of the product has been used on furniture as upholstery, looking like a carpet, cloth, or brocaded material. Design-branched foliage and architectural motifs are medallions or other centres.

Other French factories were at Fontainebleau; a tapestry atelier was here (about 1535) by François Première. Philibert Babou as manager and Serlio (Italian architect) as art director. Primatice drew the cartoons. It was discontinued as unprofitable while under the direction of Philibert Delorme during the reign of Henry II. A factory was opened by Raphael de la Planche (son of Frans van den Plancken) at rue de la Chaise, faubourg Saint Germain, Paris, on the death of his father. An atelier at Vaux (17th century) had the honor of having to work on the "Story of Constantine" and "Hunts of Meleager" designed for it by Lebrun, director of the Gobelins.

**English Tapestries.**—An existing piece of tapestry containing the coat-of-arms of the first Earl of Pembroke proves that the industry was established here already in the 16th century. It was woven by Richard Hyckes at Barcheston, who had another atelier at Wissingham. There are two tapestry maps from this weaver's hands in the Oxford Bodleian Library. The Sheldon family continued the work in the next century. William Benod (1670) had an atelier at Lambeth, London, of whose work Haddon Hall holds the "Vulcan and Venus" set (four pieces). Glenham Hall owns four "Indo-Chinese" pieces from the loom of John Vanderbank (end of 17th century), "manager of the King's Wardrobe," who also produced "The Elements" (three pieces) at Burley House; his atelier was in Great Queen street, Soho, London. Early in the 18th century Stephen Demay wove the "Hero and Leander" panels and "Acts of the Apostles," still extant, and Peter Parisot, in the same period, had an atelier at Fulham, London. The name Bradford is woven in a sofa covering of this century at Belton House.

**Morriss de Kent.**—Pierre James I smuggled into England 50 expert Flemish weavers and established, in 1619, a tapestry factory at Mortlake. Sir Francis Crane was the instigator of the movement. Orphans from the "Foundling"
1 Gothic Tapestry (15th Century)
2 "Flora" — Flemish Tapestry (17th Century)
3 "Summer," American Tapestry from the Baumgarten Ateliers
4 Flemish Verdure (17th Century)

(By courtesy of Wm. Baumgarten & Co.)
were apprenticed under the superin-
tendence of Philip de Maecht, a Fleming. His sons were marked P. D. M. often. De-
ree done by Francis Klein (or Cleyne) in 1699. The king's promised financial assis-
tance was not forthcoming and Sir Francis sank all his capital, made an appeal for money to pay overdue wages to weavers. The Prince of Wales gave some assistance and obtained some funds for the enterprise. On the king's death (1702) his heir, Charles I, aided further (as when and Crane was repaid his cash losses in 1690, while the factory became a success. England produced the finest tapestry work (it was always in demand in Flanders and France), and the Italian art designs and Flemish ornamental style, for 10 years, brought forth the finest tapestry pieces the world ever saw. Sir Richard Crane, on the founder's death in 1705, carried on the weaver's successful business and the beheading of the king injured it and quantity of the work. Sir Gillingham, under the Commonwealth, headed the factory. A Hampton Court Mantle depicting the labors of Thebes with two heads, cheaper and poorer tapestries from Italy and the Netherlands were more popular for the war-impoveryed people, however, and the factory closed in 1703. Mortlake repor-
taphael's great "Acts of the Apostles" order designs by Van Dyck; Rubens' of Achilles in six pieces; Cleyen's of Vulcan and "History of Hero and Leander". "Vulcan's Complaint to Jupiter" is an heric collection (loaned to the Metro-
Museum of Art, New York); the Royal collection owns "Hero and Leander" (five pieces); "Vulcan and Venus" in the French National Collection and Vichy; "Naval Battle of Soleby" (three is in Hampton Court; three sets of "Acts of the Apostles" are in the collection.

In 1881 William Morris founded The Gothic Works, "The Goose Girl" from a German cartoon, being the first produc-
tion (12 pieces) is in Cluny Museum. Among the best known Merton pieces are the Holy Grail (in St. Michael's, "The Seasons" (Victoria and Albert); "Star of Bethlehem" (in Oxford); "Gothic Looms.—The Santa Barbara (Mad-
sider opened, in 1720, under patronage of V, with the Jacques Vanderhogen from the Baroque, as experts. Some of the 12th century 92 pieces, woven from 45 of Francisco de Goya, are in Escorial others in the Prado. The factory is operation.

in Looms.—In 1716 the Imperial Works was founded by Peter the Great with Behac and Beauvais operators as the prime weavers. These Tapestries are of very delicate design, but very rare, hence few copies are known. Beauvais Looms.—William Baumgarten, started some tapestry looms at 321 Fifth avenue, New York City, with M. Fous-
dier as manager. After several pieces had been finished (one in the Field Columbian Museum, Chicago), the industry was moved to Williams-
bridge, a suburb, and more weavers from Aubusson, were engaged. A $20,000 set of wall panels and furniture coverings (after Boucher) was produced for P. A. B. Widener of Phila-
delphia. It took 13 months to execute. Next were some wall panels in the directors' room of the New York Life Insurance Company. Beautiful work has been done for such patrons as Mrs. Sheperd of Scarborough, Jacob H. Schiff, Charles M. Schwab, J. B. Ford, D. G. Reid, etc. Here also are produced floor pieces in Aubusson pile style.

Extant Masterpieces.—Of Gothic verdure we have in America (Metropolitan Museum, New York and elsewhere) "Baillée des Roses"; "Capture of Jerusalem by Titus"; Cluny Museum has "Lady of the Unicorn"; Victoria and Albert Museum (London) has the "Four Combatting Scenes"; before the World War Rheims Cathedral had "Coronation of Clovis"; "Capture of Soissons," "Story of the Wonderful Stag," "Victory over Gondebout," etc. Of Gothic tapestries dating from the 15th century, there are in the Cathedral at Angers a set of seven "Apocalypse"; in the Brussels Museum were "Four Philosophers," "Abraham and Isaac," "Presentation of Infant Jesus in the Temple"; in Halberstadt Cathedral, "Christ and Apostles"; pieces (fragments) from the Saint Gereon Church, Cologne, are in museums at London, Lyons, Nuremberg. Arras productions of this period, known and identical, had become reduced to a single set before the war; the "Story of Saint Piut and Saint Eligius" in Tournay Cathedral. Late Gothic examples are in the Louvre, "Last Judgment," "Combat of the Vices and the Virtues," "Creation," "Triumph of Christ," "Christ Inspiring Faith," "Scenes" from New Testament, "Creation," two David tapestries in Brussels Museum; "Story of David" in Cluny Museum. Transition Gothic-Renaissance pieces extant: in Rheims were "Story of Saint Remi," "Story of the Virgin"; "Story of Saint Stephen" (nine scenes); "Last Supper" (10 scenes) in Aix-en-Provence Cathedral; "Life of Christ" in La Chaise-Dieu (both latter 14 pieces). All are without borders. Renaissance pieces are "Acts of the Apostles" in 10 pieces in Beauvais Cathedral, French National Collection, Hampt-

Tapestry Characteristics.—In identifying the location of the weave special attention is given to the border, because special borders were designed for replicas of the original pieces. The tape border or binding, known as the "gal-
loon," often contains the marks of the weavers, but they are often absent. The primitive design is characteristic of Gothic tapestry, such as the Byzantine "stiffness" of expression and "flattening" in clothing, the "fatness" or absence of what artists term "atmosphere," the lack of perspec-
tive. Early works (14th and 15th centuries) usually have but a single subject, few personages. Pointed Gothic architecture in the piece places its period, as do the capitals and shafts of columns. Of course, Renaissance tapestries display florid columns. The earliest pieces have no border—these early ones have simple flowers filling spaces. To find one borders is of great assistance; when armor appears the style affords a good clue. Much may be proven by the makeup of the lettering. Renaissance pieces are devoted to classic subjects, battle scenes, kings, queens and their courts. Borders are a clue; earliest were of woven tape (gallloon) in a single tone. Then came frames of fruit, flowers, foliage (also ribbons sometimes), they are Gothic. Next we arrive at scenes depicted in square divisions, they are Renaissance. The relative value of the border keeps growing as well as the size, and, by the 18th century, we have the central subject actually crowded for space to make room for the elaborated border subjects. In Louis XV tapestries we arrive at actual gold picture frames in textile, moldings and all.

Tapestry Marks.—The first producers’ marks appeared in 1528, when Brussels passed the ordinance by which each piece had to have the town mark, *a heraldic shield between two B’s* in either capitals or minuscules. The two B’s either face the same way or, sometimes, the left B is depicted backwards. It appears on the galloon and generally in a lighter tone than the body. There was also the merchant’s mark. This law only affected those pieces of about 13 feet or over, not the small ones (which were few in early days). In the pieces from the Spanish ateliers of Wilhelm de Panemaker his W P is found in several confusing combinations, and the number 4 frequently is found combined with the W. The initials JG are said to be the forename mark of Jacques Guthe. The Bruges ateliers used two B’s traversed by a crown. A gonronne of four in a shield or circle was the mark of Pierre of Enghien. In the 17th century we find initials (frequently, as two C’s intertwined for Charles Coomans) and C. monogram for Alexander Coomans; J. F. for Jean Lefêvre; P with a fleur-de-lis stood for Paris. A fowl roasting on a spit was the Jean Rost sign; Florence used a lily; Mortlake a shield with a cross entire; Tournay a castellated tower; Lille a peculiar shield charged with a lizard and side initials L and F; Amiens used a double S entwined; Beauvais a red heart, white pale and two B’s; Munich a shield charged with a child standing with arms outstretched on white background (field).

CLEMENT W. COLIN

TAPESTRIES, Manufacture of. A rect history of tapestries has been written by many European and by a very American savants. The rise and fall of merous ateliers and of tapestry-weaving have been traced, quantities of marks and ograms deciphered, long lists of names discovered and the technical processes of weaving at the different eras defined, but the general history of these art products remains great extent unwritten. In evidence of the interesting results research in this field may unfold, the arguments of a learned Frenchman in an essay which appeared some years almost tempt one to believe that the tapestries woven by Helen and Andromache, to represent the principal episodes in the siege of Troy actually inspired the 'Iliad' and the 'Odys.' We have become fairly well acquainted with the social position tapestries occupied in different nations since the dawn of civilization, by the impressions they made upon the public taste from age to age and by reading the history of the roles they filled on hundreds of occasions of pomp and ceremony during succeeding centuries. We have also been fairly well acquainted with the changes in the style and character from the infancy to the maturity of the art, and we are fairly well acquainted with the ideas they expressed throughout this period, by patient research among documents from the great centres of production, by the inventories of princes and potentiates and from newly discovered correspondence. Concerning individual ateliers the facts which had been long forgotten, but which may be known to all by careful study of the existing sources wherever they can be found. Gueffey, Pinchart and Wauters have long since shown that tapestries often exhibit the most loftyest conceptions of many of the greater artists, that at all epochs the most eminent designed models for them, and that with an insufficiency of the existing records of whole schools of production, which they would have been lost to the world if it had not been for the additional action of the characteristics and manner in which the ideas and sentiments of the artists, which they created, and, therefore,
possible to separate the history of paint-
that of storied tapestries.

Tapestries, or calling them by the French name — "Arras" — are decorative or designs in tissue which are made by weaving variously colored wool threads dyed or woven in an entirely different manner. The entire design is made up of different threads with the aid of a loom. This interweaving is done with a "broom" in French, which is a shuttle nor a bobbin, but partakes of the nature of both, and for which there is no equivalent word in English. The picture is developed upon the warp by the color of the wool threads. Needles are used in weaving tapestries. In the case of weaving the wool becomes practically integral portion of the completed structure. Art tapestries can only be woven by artists who, in the best periods of the ages, interpreted and never copied a thing. Their work cannot be altered nor imitated, but naturally was affected by those who saw other things in different qualities of fabrics; since they have not each piece possesses a distinct origin and is not a mechanical repetition of the subject; and since every thread of the web is incised by those laws that the warp is invisible on either side of the tapestry. The kind of tapisserie and machine-woven which masquerade under the same name, people who can work such skill that the distinguishing from fabrics; since they have no use each piece possesses a distinct origin and is not a mechanical repetition of the subject; and since every thread of the web is incised by those laws that the warp is invisible on either side of the tapestry. The kind of tapisserie and machine-woven which masquerade under the same name, people who can work such skill that the distinguishing from fabrics; since they have no use each piece possesses a distinct origin and is not a mechanical repetition of the subject; and since every thread of the web is incised by those laws that the warp is invisible on either side of the tapestry. At Gobelins they weave only in haute-
1d at Beauvais, Aubusson and Moline, basse-lisse. In both kinds the warp is stretched on rollers so that they keep taut and parallel like the strings of a harp, but naturally work in an entirely different manner. As there are usually 22 to 26 of them. In the process of weaving both sorts hang in loops or in which the threads are different tones of color. In haute-lisse one end is attached to another warp in each relay, at a slight distance above the other end. Assistance of these strings called "lisses" imparts the warp threads backward and from right to left between as many or of them as he desires with his right hand. In basse-lisse these threads are attached to mechanical contrivances to pedals at the loom so that the weaver raises and lowers the threads with his feet, and both hands free to pass the broche, he has about one-third faster than the weaver in haute-lisse.

Frugality and Cost of Weaving.—The number of warp threads which are covered by the warps of the broche and one thread of the reel only as many as are included in a shade or tone of color. In background scenes and skies the woof-thread may cover at each pass from 30 to 60 warp threads, but when personages or their costumes are represented it rarely covers more than two or three of them. In short, it is the manifold changes in the coloring, lights and shadows, the half-tones, and so on, by which the artist can weave only about a yard square in a year. At the Gobelins, to-day, this yard square costs about $800, which does not include taxes, insurance, interest on cost of plant, rental for the apartments of the weavers, etc. The weaver passes from light to dark colors and from one shade or tone to another by weaving in threads of intermediate shades or tones in formations like the teeth of a comb and thus avoids the mosaic effect which would follow weaving in different threads. This is not done by side. This process is termed hatching the colors, and is one of the most difficult feats in tapestry weaving. In valuable antique tapestries the colors are usually hatched with colored bars or with parallel lines. The eye does not readily discover where the different shades of the same color begin or end.

Difficulties of Weaving.—In both haute and basse-lisse the weaver works on the wrong side and the finished part faces away from the loom. Consequently he is unable to criticize the progress of his work unless he walks around to the front of his loom in haute-lisse, and unless he raises it from its horizontal position in basse-lisse. In haute-lisse the cartoon is placed behind the weaver, and in basse-lisse it is placed beneath the warp. The weaver in haute-lisse translates the cartoon by sight, with nothing to direct his eye but the outlines of it that he has traced upon the warp, but he can, by walking round to the front of the tapestry, or by the aid of a mirror while seated take constant note of his work, and even make slight modifications in it. The weaver in basse-lisse, seeing but imperfectly what he translates, as the warp threads hide the cartoon to a certain extent, cannot examine his work, except at considerable trouble, until the tapestry is finished, when it is too late to remedy any defects. Naturally, therefore, the artist in haute-lisse has greater opportunities for noticing the effect of light and shadow and can more readily interpret or idealize the cartoons according to his own conceptions than can his brother in basse-lisse. For these reasons haute-lisse tapestries possess as a rule greater artistic value than basse-lisse. It may be said in a few words that haute-lisse are mostly creations from, and basse-lisse are mostly reproductions of, their respective cartoons.

The precautions taken by the weaver to verify the correctness and excellence of his work are, however, of little advantage if he does not possess the specially developed talents as well as the necessary skill and experience to insure success in his interpretations. He uses dry and supple materials which cannot be manipulated as readily as the semi-liquid colors of the painter, nor can the thickness of
these materials be increased or diminished at will as can paints upon canvas. He cannot correct nor alter, nor even materially modify what he has done, nor erase and begin again, as the painter. He cannot varnish his production, nor employ any other of the multiplied accessories of the brush and the palette. His work grows almost imperceptibly and he is, therefore, unable to seize the general effect of the entire composition in any other way than mentally. He cannot obtain transparency and harmony except by the complicated process of hatching the colors, and must be exact in choosing them and measurably correct in his drawing, although working grace on the wing side. He can improve slight faults by packing the wool threads more or less closely together with a special kind of comb, but he cannot change faults in color or in drawing except by unweaving the defective part and renewing it thought. Is it any wonder that it takes at least 12 to 15 years to educate a novice in all the mysteries of the profession and that it took several generations of master-weavers to perfect the art of weaving storted tapestries? The tapestry that is woven from a basse-lisse tapestry, and the amateur even is often at fault unless there should be a manifest defect visible, like a mark, monogram or inscription running backward. Since the cartoon in basse-lisse is placed beneath the warp, it is the finished tapestry, and its subject is, therefore, reversed in the process of weaving, just as your signature or any other bit of writing is reversed on the blotting pad with which you dry it. No marks, monograms or inscriptions were usually painted upon the cartoon, consequently the weaver, after completing the design, took of some of them in as he would write them, which naturally made them run backward in the finished tapestry. In basse and haute-lisse interpretations of the same cartoon, the subject faces the spectator in the former in an opposite direction from which it faces him in the latter. To avoid this difference it has been usual for a long time to furnish the basse-lisse weaver with a reversed model of the cartoon so that the scheme of the tapestry when finished was reversed. It is the practice to divide the cartoon at will. Any one can, however, occasionally detect a basse-lisse tapestry on closely scrutinizing it with a microscope on the wrong side, by finding here and there the hairs from a man's beard. This may seem ludicrous, but the ancient basse-lisse weaver, according to existing illustrations, usually wore a full beard, and when he bent over his work to catch glimpses of the cartoon beneath the warp, he occasionally caught a hair or two of it between the threads of the warp and the wool. There are a number of embroideries mis-called tapestries, notably the historical Bayeux frieze which many authorities assert was made by Queen Matilda of Normandy, and her maids of honor, although there are many others which serve to reproduce it with. It is needlework, and in no sense a tapestry.

History of Weaving. The art of weaving tapestries was understood in the remotest ages, and was discovered but little later than the art of painting. Weakening and diluting with the spirit of decoration manifested itself almost everywhere long before the dawn of civilization. It is a long way from the coarse and creampile used in ancient times by many ing tribes in the decoration of their sumptuous abodes. It was versely employed by the rich and noble, 15th, 16th and 17th centuries to enhance splendor of their palaces; nevertheless the student will find ample opportunity for thought and gratification in every elucidates the progressive steps in the long march. In short he will find a study of tapestries will lead him into which were practically closed for 100 years that it will open his eyes to new views of the race. Not the mere excursion into this field, the most ancient visible evidence of manner of weaving tapestries, but the art upon the walls of the hypogeum of Beryan el-Gadin of a painting finished about years before the birth of Christ, upsetting various calculations, since it represents two sons weaving at a loom very similar in respects to those of the olden time. There is a tradition among the Hebrews that the art was invented by the daughter of but some of the ancient philosophers and of the ancient poets claim that the hortel to Phanphil, daughter of Apollo, though Pliny the younger in his graphic tells that the sumptuous beauty of the industrial andactive products of his era yet he is unfort silent upon the manner in which they woven, and the probable inventors of them. Ovid, on the contrary, is definite and explicit and not only gives the origin of the art, in his description of the Lydian maiden and the goddess Ariadne, but judging by his psychological process, one could well believe he describes the manner with which the work is woven at the Gobelin's to-day. Accord the story Arachne was exceedingly vain dexterity in weaving and challenged him to a trial of skill. The outraged goddess accepted, but wove no better than the sumptuous damsel. Each attached the beam and passed the slender broches out among the threads. Minerva who scenes of her contests with Neptu Arachne the love exploits of Jupiter goddless could not forbear admiring the work of the maiden, although enraged mortal should have dared to compete immortal. In her anger she destroy tapestry of Arachne, struck the damsel forehead with her broche, metamorphose into a spider, and lady her weave on f

Oldest Tapestries. The oldest mural tapestries are no doubt the frescoes from the Church of Saint Gereon in Bologna, which were woven in Europe in the 12th century. The oldest tapestries are no doubt those discovered in Crimu by Stephan, thearcheologist, who believes they were woven in Asia 400 years before the Christian era. The oldest I have ever seen are of cloth of gold, and were found in tombs of ancient Egyptians. They were in haute-lisse and are presumed to
The 9th centuries. Coptic tapestries, in so far as known, in decorating houses there is no evidence that any of them were used as ornament houses. In consequence, the most valuable and important collections of storied tapestries are those in Paris, Madrid, Florence and Vienna. In each collection, except the last named, there are about 600 pieces. That in Paris is largely composed of tapestries woven in Flanders and is unrivaled in its magnificent specimens of Gobelins and Beauvais manufacture. That in Madrid is largely composed of those woven in Flanders, and is remarkable for its wealth of superb Flemish specimens. That in Vienna is not as large as those in Florence, Paris or Madrid, but includes tapestries woven in all the great centres of production, although, as in Madrid, those woven in Flanders are in the majority. That in Florence is composed of nearer equal proportions of the products of France and Flanders than any of the rest, although the Italians claim that almost one-third of it was woven in Italy.

Flemish Art.—The work of the Flemish weavers, studied in its entirety, constitutes an immense epic in warp and woof, illustrating religious and profane history, mythological episodes, legends of the saints, creations of the poets and novelists and celebrated acts of great men of all ages. Her master-weavers, however, did not confine themselves to these inexhaustible sources, but made admirable representations of nature's models, for, the truthfulness of their landscapes, the repose, softness and veracity of their background scenes, and the purity and reality of their garlands of flowers and fruits have received the unbounded admiration of connoisseurs for generations. Some of the historians of tapestries have failed to award Flanders her just rank as the greatest of all centres of tapestry weaving. For over three centuries she eclipsed all others in the magnificence and excellence of her products and in future ages when the tapestries of the latter part of the 18th and all of the 19th century have passed into oblivion, amateur and connoisseur will still recall the glory of her ateliers and still go into raptures over the tapestries which issued from them during the 15th, 16th and 17th centuries. During these 300 years she led the world in the production of practically perfect examples of textile painting, that is, tapestries which are rich in color, strong in decorative effect, graceful in drawing and with subjects adapted to the exigencies of the loom and the aesthetic requirements of wall decorations. Her tapestries of the first half of this period rarely contain more than 30 to 50 different tones and shades of color, the half tints and graduations having been made by patching one color into another. In the 16th century Flemish tapestries reached their apogee. Her master-weavers, from their profound love of their art, wove as if inspired and painted both grandly and broadly in tissue. By careful and intelligent study they absorbed and interpreted even the mores of those to which the artist would apply. From ancient art they designed the models and “often further idealized the latter's ideals.” Naturally, therefore, the productions of Flanders outvalued those of any other part of Europe, but about the middle of the 17th century she was obliged

Museums.—There are only two Europe devoted exclusively to the tapestries and textile products, to Gobelins in Paris, and the Croceta in Milan. Although some of the remarkable collections, their tapestries exhibited in the royal or lace, or in the museums among the collection of art. Those exposed at the have been selected with especial care piece shall be an object lesson to the student, enable him to distinguish the modifications in the methods of weaving at different epochs, criticize the results, and become acquainted with the changes from the first foundation of the Gobelin in 1663 to the present day.
to bow her proud head to her rival—Paris. As the taste and demand for tapestries grew, most of the sovereigns of Europe determined to establish ateliers for weaving them in their respective territories, but nearly all were obliged to depend upon Flanders for master-weavers capable of carrying their resolutions into effect. France was the only exception of any note, for the art of weaving tapestries had been introduced in that country at probably the same period as in Flanders. Although the French ateliers had endured all through the long years of her wars with England, yet the best of them had not succumbed. Under the fostering succor of Francis I and Henry II they showed renewed signs of life; under the wise policy of Henry IV and Louis XIII they gathered additional strength, and under the magnificent support of Louis XIV they out-rivalled all competitors. Nevertheless Henry IV summoned celebrated Flemish master-weavers to France, loaded them with honors and showered inestimable privileges upon them, which Louis XIII and Louis XIV gladly continued and extended. The object of the French kings was to increase the demand for tapestries by introducing cheaper methods of weaving then known in Flanders, as the lessened cost would bring them within the reach of the middle classes, whereas they had heretofore been found purchasers only among the rich and the great. Finally, as these kings expected, French ideas and taste prevailed and the ateliers of France grew in importance and reputation as the character and prestige of those of Flanders faded away, until all the latter were closed, leaving the field entirely to their French competitors. See Tapestries; Gorellin, etc.

Charles M. Foulke,
Lecturer and Writer on Antique Art Tapestries.

**TAPEWORM.** An elongate flattened ribbon-like parasitic worm belonging to the class Cestoda (q.v.) of the phylum Plathelminthes. In the large majority of forms the body is divided into units, segments or proglottids which are usually conspicuous externally although in a few less common genera such partitions are lacking and there are rare species in which the body consists of but a single joint or section. The tapeworms are common in all vertebrates and from their considerable size and length are the most conspicuous of all parasites. Three of the 24 species found in man are 10 meters or more in length and yet certain other species are so insignificant that they have long been overlooked. The large human tapeworms were known to the Greek and Egyptian physicians although all were regarded as of one kind and it was 1002 before the famous Basel clinician, Felix Platter, distinguished two kinds of tapeworms from man. The large bladderworms from various domestic animals were also well known to Greek writers on medicine but were considered as growths until Redi in Italy demonstrated their animal nature. They were, however, placed in a special class (Cyestia) until about 1850 Kuchenmeister by feeding experiments established their relation as larval or immature forms of certain tapeworms. The prescription placed by Moses on the use of certain flesh had its ground unquestionably in the prevalence in such animals of bladder-worms. Hippocrates writes of evacuation of pumpkin-seed-like forms diagnostic of tapeworm and Aristotle in contrast with round worms the tapeworm is attached to the alimentary canal by means of its scolex. The body of a tapeworm has at a bulbus enlargement known as the scolex which in other types has a different structure but is oval with two elongate suckers in the fish tapeworm of man and more rare with four cup-shaped suckers in the pork tapeworms of man. (Cf. Figs. 1: Following the scolex comes a very region usually undivided; this neck: It changes very gradually jointed body which becomes heavier a conspicuously divided toward the lumen where in the full grown intestinal proglottids are being regularly set free: ejected from the intestine of the host, body is highly muscular and has no hair, it varies constantly and con shape, especially at and near the neck so that the entire appearance the posterior portion may be radically modified. (1) The head may be armed with hooks as suckers, as in the human pig, designated the pork tapeworm. Most tapeworms are found in in and in man this is the only normal and the reports of their occurrence in the being purely imaginary or due to re the normal movement of the alimentary They have been found in the bile duct as the scolex embedded in the wall of the time, but all such occurrences are rare and as abnormal. The effect of this parasitism is measured first by the loss of essential which must be relatively great as the large and grows with striking rate the beef tapeworm the size is about 72 millimeters per diem which is about the formation of 13 to 14 proglottids in 24 hours. This factor is, however, inadequate for the results produced by the presence of only a single parasite. These symptoms are prominently of a reflex character and are usually explained on the position that the tapeworms pre
es which are absorbed by the host and a marked toxemia. One human tape-
worm reproduces a severe anemia of the per-
type recognized as characteristic of the
of this species, symptoms of tapeworm disease are
general and not well defined so that a
in successive segments. The large bush-like
masses are ovaries and the slender flattened
structure near the posterior margin is the yolk
gland. Between it and the ovaries lies the
small spherical Mehlis gland formerly known as
the shell gland, but incorrectly designated as
such since investigations show that the material

The abundance and distribution of ns are not accurately known and a data exist only for a few localities : selected groups such as hospital inmates of public institutions and
French maritime hospitals reported in ut 1.5 per cent of all cases were treated worm infections and the United States service during the Civil War recorded 12 per cent treated for tapeworm, a hat is certainly much lower than the ree of infection in this country.
bladder worm, or larval stage in the y of the tape worm, is found encysted flesh of a great variety of hosts. It trance to the final host when the flesh ing the cyst is ingested. When set digestion the bladder-worm everts the d neck region which were formed in fashion on the inside of the hollow l or oval larva. The bladder itself is but the chain of proglottids grows out : neck.
beef tapeworm (*Tenia saginata*), also abe unarmad tapeworm of man because ex is devoid of hooklets, inhabits the testine of man but has not been found other host. The bladder-worm (*Cyrti-
ica*) occurs in the muscles and viscera . As is natural from the cosmopolitan ion of both hosts this parasite occurs : entire world but is more common in gions where the habit prevails of eat: underdone or rare. It is also ince-rf eqency as shown by the statistics of 1ch maritime hospitals which report 33 mong 130,927 or 0.2 per 1,000 during and 1886-90, 2,253 were infected among or nearly 75 times as many as at the late. Attention has already been called read of this tapeworm which with the highly muscular and variable in form. reductive organs are not visible except strands of tissue in full grown pro: they have the form represented in The numerous small round masses are es which communicate by branching with the common sexual pore at the enerally speaking these pores alternate

Fig. 2.—Sexual organs in a tapeworm segment (*Tenia
saginata*).

Fig. 3.—Free proglottids of A, *Tenia solium*, and B, *Tenia saginata*. for the shell comes from the so-called yolk gland or vitellarium. At this stage of development the uterus appears as a median sausage-shaped receptacle. When the eggs accumulate it is increased in size so greatly that numerous lateral branches are formed extending almost to
the margin of the proglottid, giving the aspect shown in Fig. 3.
The segments of this tapeworm when evacuated are little more than sacs covering the much branched uterus which is crowded with eggs. They possess considerable power of independent movement and are frequently found at some distance from the point of deposit. The eggs have several coverings which
serve to protect them even after the disintegration of the proglottid. Distributed by chance an egg reaches the stomach of an ox with the food or drink of a man. Under the stimulus of the gastric juice the membranes are ruptured and spherical six-hooked larva escape. It bores its way through the wall of the alimentary canal and comes to rest in the connective tissue. When it reaches a suitable location it develops by growth and the accumulation of a considerable amount of fluid in the centre to a bladder-worm. A thickening of the wall of the bladder produces an ingrowth in which is formed in reverse the head of the future tapeworm. Growth is slow and in six months the worm measures only six millimeters or less in diameter. If the flesh containing the bladder-worm is consumed by man while the parasite is still living the head of the bladder-worm is everted and it attaches itself to the wall of the intestine and begins to grow into a mature specimen. This period of growth requires no more than 9 or 10 weeks for the production of mature proglottids. Since a moderate temperature is favorable to the bladder-worm in well-cooked meat it cannot possibly carry the infection. Exposure to cold storage conditions for three weeks is also adequate to destroy all the bladder-worms contained in a piece of beef.

The pork tapeworm (Tania solium) is known as the armed tapeworm of man because of the crown of minute hooklets which is found on the anterior face of the scolex. Like the preceding species it is confined in the adult condition to the small intestine of man. Its bladder worm (Cysticercus cellulosae) occurs in the muscles and viscerina ordinarily of the pig from whence the common name of the parasite. It also occurs in the dog, cat, rat, ape and rarely, also, in man. While the distribution of both parasite and bladder-worm is as broad as that of the previous species yet there are certain parts of the world where it is entirely wanting, i.e., among those people who do not eat the flesh of the pig. The species is common in European countries where pork is consumed in the smoked but uncooked condition and is very uncommon in the United States because of the general practice of eating pork well done. The parasite is somewhat more slender than the beef tapeworm. The terminal proglottids (Fig. 3) show that the branches of the uterus are less numerous and heavier than those of that species, but to distinguish between them is not always easy. A positive determination can readily be made when the scolex is obtained because of the presence of hooks in a double circle in which they alternate regularly in size. In general the pork tapeworm is less muscular and more transparent. Its life history is similar except that the eggs find opportunity for hatching and development in the pig rather than in cats. The species is more dangerous than the preceding form because of the fact that the bladder-worm may develop in the human host. Apparently the brain and the eye are the points in which they have been most frequently observed and the cerebral cysticerci are most dangerous because they produce naturally conditions similar to brain tumors and are not infrequently the cause of sudden death. There are no special symptoms connected with presence and usually it is not possible to distinguish between them and tumors of different origin. The bladder-worm displays in situations a marked longevity as the individual has been followed by means of ophthalmoscope for 20 years in the human Because of the campaign against the pork except when well cooked this parasite grown much rarer within recent years.

The dwarf tapeworm (Hymenolepis nana) is the most numerous parasite of this kind found in man in North America. It is recognized as identical with a species that occurs in rats as well as in rats (H. nana). On account of its size it was not discovered until the mid-late last century and while even yet it is frequently overlooked it is present at times in enormous numbers. It may justly be cons slender cosmopolitan in its distribution. Cases in general under unfavorable hygienic conditions and infection is probably traceable to contamination of food by rats and pigs. The worms are usually found in considerable numbers and excite digestive disturbances marked severity. Diagnosis is made by a scopic demonstration of eggs in the treatment should be in the hands of a physician. The records of Ransom concerning American cases indicate the great frequency of the parasite in children and especially infants.

One of the smallest of tapeworms is H. echinococcus which is a parasite of The chain consists of only three or four proglottids. The parasite is important because of the character of its larva or bladder-worm which is known as an echinosomes (Echinococcus polymorphus). This bladder-worm develops in a very large number of hosts and provides a complex structure with secondary and tertiary bladders in great numbers so that the mass assumes enormous proportions. It is one of the most frequent causes of intestinal obstruction because the tissues involved may be fig. 4. Hymenolepis nana: A, Scolex \times 15, B, Female, in extended and contracted conditions. Character to prevent surgical treatment. It was brought about by the use of certain compounds and to the general practice of removing the tapeworm by surgical means other methods of treatment have recently been tried with some success. This and numerous other parasites owe
TAPIOCA — TAPIR

T. Dibothriocephalus latus, known as the fish tapeworm. It occurs in the small intestine of man and other mammals. The larva is found in the flesh of various animals, including dogs, cats, and rabbits. The adult tapeworms live in the human intestine and can cause severe illness.

TAPIR, a member of a family (Tapiridae) of hoofed mammals, allied to the horses and rhinoceroses and chiefly distinguished by the fact that the nose is prolonged to form a short proboscis or trunk and the front feet have each four toes, the hind feet possessing three toes only. The little toes of the front feet are unsymmetrical and do not touch the ground, while all the toes are "hoofed." They are adapted to live in swamps and rarely leave the forests covering such wet places. The tapirs possess a very wide distribution and inhabit both the Old and the New World. The best-known species is the South American tapir (T. terrestris), which inhabits the tropical forests of South America and is chiefly found living on the banks of rivers, in which it swims and dives with great ease. It is chiefly a nocturnal animal, feeding on roots, fruits, and leaves. The adult is colored brown, the young being variegated with lighter spots and stripes on a darker ground. The hair is short and thick, but the neck possesses a short black mane. The average length is from four to six feet. A second species of South American tapir is the T. villosus, which is distinguished chiefly by the greater length of its hair, due to the fact that it inhabits elevated foot-hills of the Andes, where the climate is cold.

The only other distinct species is the Malayan tapir (T. Malayanus or Indicus), found in Malacca and Sumatra and known by the white color of the hinder part of its body, the head and anterior portions being black. The proboscis is larger in the Malayan species than in the South American form, but the former has no mane. It is usually of larger size than the New World forms and appears to be a shy, retiring animal, inhabiting clumps of brushwood.

The existing tapirs seem to approximate more closely than any other perissodactyls to the primitive (Eocene) type of that group. The family, as at present defined, dates back to the Lower Miocene and its remains are found in the White River beds of that age in the Rocky Mountain region. The earliest are separated as the genus Tapiris, but typical tapirs soon appear. "It is thus evident," remarks Woodward, "that during Miocene and Pliocene times these animals ranged over most of the warm and temperate lands of the earth's sphere. Hence is explained the remarkable distribution of the existing tapirs, which are confined to two widely separated areas, namely (1) certain portions of the Indo-Malayan region, and (2) the tropical parts of America. Like the surviving dipnoan fishes they are an illustration of a once dominant race nearly exterminated, but still struggling for existence.
TAPPAN, Tappan, Arthur, American philanthropist: b. Northampton, Mass., 22 May 1786; d. New Haven, Conn., 23 July 1865. He accumulated a fortune in the dry-goods business in New York and became noted for philanthropy. He was a founder of the American Anti-Slavery Society, endowed the Lake Seminary in Cincinnati and aided other educational institutions. In 1828 he founded the New York Journal of Commerce and in 1833 established The Emancipator. He was an ardent abolitionist and a president of the American Anti-Slavery Society, to which at one period he contributed $1,000 a month. He aided fugitive slaves to escape from the country and procured the release of William Lloyd Garrison when the latter was imprisoned in Baltimore, by paying his fine.

TAPPAN, Benjamin, American naval officer: b. New Orleans, La., 10 April 1856. He was graduated from the United States Naval Academy 1876 and in 1886 was commissioned lieutenant. From 1888-91 he served in the office of the Bureau of Naval Intelligence and from 1891-94 on the hospital ship. He was stationed at the Brooklyn navy yard 1895-96 and while on board the Raleigh participated in the battle of Manila (1898). During the attack on the city of Manila he captured a Spanish battery and for this act was advanced five numbers by President McKinley.

TAPPAN, Eva March, American educator and author: b. Blackstone, Mass., 26 Dec. 1854. She was graduated from Vassar College in 1875 and was a Fellow of the University of Pennsylvania. She published 'Charles Lamb, the Man and the Author' (1896); 'In the Days of Alfred the Great' (1900); 'Our Country's Story' (1902); 'In the Days of Queen Victoria' (1903); 'Canada's Story' (1903), etc.

TAPPAN, Lewis, American merchant and philanthropist: b. Northampton, Mass., 23 May 1788; d. Brooklyn, N. Y., 21 June 1873. He spent several years in commercial life at Boston, then (1827) settled in New York as partner of his brother, Arthur. Both took a very active part in the anti-slavery cause. Lewis and his brother were among the founders of the Journal of Commerce (1827) and (1828-31) Lewis was sole proprietor. The pro-slavery mob, in 1834, sacked his residence. He aided in the organization of the American Missionary Association, acting as treasurer and president for a number of years. His firm failed in the crisis of 1837, but later met all indebtedness. After the failure he established the first mercantile agency in this country and remained its head for a number of years. He published his brother Arthur's 'Life' (1871).

TAPPAN BAY, or TAPPAN SEA, the name given to the expansion of the Hudson River near Ossining and Tarrytown, N. Y. See HUSSON RIVER.

TAPPEN, Frederick Dobbs, American financier: b. New York, 29 Jan. 1829; d. Latham, N. Y., 28 Feb. 1910. He was educated at Columbia Grammar School and New York University, graduating in 1849. Next year he entered the National Bank of New York as clerk, rising by 1857, at which time the bank was reorganized (1865) as the National and Tappan became president in 1869. He became member of the conference committee with the New York Clearing House in 1889 and member of the committee in 1877 was appointed (1873) member of a committee to suggest financial reforms in operation between banks. Then and later he wrote about clearing-house reforms in practice and was in the 1893 crisis Tappan rendered important service; by June business paralysed and business corporations, banks, roads, etc., had a $2,000,000,000 liability gold in the treasury at low ebb, but the Clearing-House Association decided the bank could be maintained by extension of credit which was averred. Later he rendered useful service in times of panic.

TAPI, tap'tē, India, a river rising in the Mahadeh, flowing westward into the Gulf of Cutch, is 430 miles long and navigable for a short distance.

TAPUL, tā-pool', a group of islands in the Sulu Archipelago, Philippines, lying off the coast of Luzon. The group is the northeast and of the Tawi-Tawi group on the southwest, consisting of three islands named and some uninhabited; area, 77 square miles. The more important of these islands is the (q.v.), the largest, in the southern part of the group; (2) Bolilong, the most northerly of the group, heavily wooded; elevation 1,344 feet; area, eight square miles; (3) Lapat of Siasi, from which it is separated by a narrow channel, with a very rugged surface; elevation, 1,344 feet; area, seven square miles; (4) Tapul, the name island, the most north of the group, fertile and under cultivation, highest elevation, 1,636 feet; area, six miles. Though all tropical products and motion flourish in the larger islands, the industry is mother-of-pearl, pearl and fishing; there are coconuts plantations of great value, on one of the islands. Trade is carried on by Sulu, Tawi Tawi and Borneo. Pop. (1901) 3,000. See SULU.

TAR, a thick, very dark liquid obtained by the destructive distillation of vegetable substances. That obtained from peat, bituminous shale, etc., is called coal tar, while that from wood is named wood-tar. Both are very complex mixtures of substances. The substance popularly known as tar is wood-tar.

Coal tar is collected from the hydrates and condensers of the gasworks and contains a large amount of carbon, acid and base substances. Its components are first separated in a rough way by distillation and are then fractioned to an extreme chemical treatment to purify each substance therein. Of the various acids, the most valuable are the maleic.

A HEEL STATE, a popular nickname to North Carolina (q.v.).

RA, tā-ra, Ireland, a hill in County six miles east of Trim. According to the fes of Tara, the traditional con-here, was established by Olram Fod-Ollay Fola (b.c. 900 or 950). After the is of the meeting the princes and others held a banquet, each guest seated he-shield which the heralds had sus-on the walls of the great hall. The of Tara, tradition says, was 900 feet and had 150 apartments and 150 dormi-The hall had a capacity for entertaining quests daily. It was here the early kings and were crowned. King Cormac Ma-d century A.D.) is said to have founded here of military science, law and litera-In the days of Saint Patrick, Tara is have been the principal seat of Druidism ra and (about 500 A.D.) fell under se of Saint Ruadan and had to be aban-as a royal residence. A battle here is have caused the fall of Danish rule th in 980. In 1798 the Royalist troops, ang, defeated 4,000 Irish insurgents, 56, at Drumore O’Connor. After the city had supported the insurgent re here 15 Aug. 1843, at which it is said persons attended. The so-called re-mains of the royal palace are represented by six raths or circular earthworks, of which the rath-na-riog (king’s rath), which is the most extensive, contains the forradh (meeting place) which consists of an oval level summit. The “stone of destiny,” on which the kings are said to have been crowned, is located here. Certain earthworks enclosing a space about 759 feet by 46 feet and having bases at intervals supported by have been the entrances are considered as having been the banqueting hall. Thomas Moore rendered the Tara tradition imperishable with his poem “The Harp That Once Through Tara’s Halls.”

TARAI, tā-ri, or TERAI, India, a moist, jungly and unhealthfull tract of land running for several hundred miles along the southern base of the central Himalaya. See HIMALAYA.

TARANTELLA, a swift, whirling Italian dance; so-called because it was popularly thought to be a remedy against the supposed poisonous bite of the tarantula spider, which was said to set people dancing.

TARANTISM, or TARANTISMUS, dancing disease (q.v.).

TARANTO, tā-rantō (Latin, Tarentum; Greek, Taras), southern Italy, a for the province of Lecce, at the northern angle of the Gulf of Taranto, on a rocky tongue of land which separates the ancient inner harbor, a sort of lagoon called the Mare Piccolo (Little Sea), on the east, from the open sea on the west. The side has been made an island by a canal on the southeast, crossed by an iron swing-bridge, which admits the largest war vessels; another bridge at the northwest end also connects it with the mainland. Two islands, Saint Paolo, with a fort and a lighthouse, and Saint Pietro, guard the entrance to the outer harbor. The streets are very narrow, the three principal being the Strada Garibaldi along the Mare Piccolo, inhabited chiefly by fishermen; the Strada Maggiore, in the heart of the town, the main business thoroughfare; and the Strada Vittorio Emanuele, along the sea-front, a fine promenade. The 11th century cathedral, now wholly modernized, and the old castle are the chief objects of interest in the town proper. The Borgo Nuovo, a suburb on the mainland to the southeast, occupying the site of ancient Tarentum, contains a large arsenal and naval hospital and various harbor works have been constructed. The fortifications of the town have been much strengthened since 1863. There is an export trade in oil, wine, licorice, fruit; and coals, grain, petroleum, etc., are imported. Tarentum was founded by Greeks in 707 B.C., and rapidly became the chief city of Magna Græcia. It was noted for weaving and for the purple dye obtained from a species of mussel. It reached its greatest prosperity under Archytas, the philosopher, in the 4th century B.C., after which luxury and vice caused it to decline. It was compelled to seek the assistance of Greek kings in its wars with the Lucanians and when attacked by the Romans it was assisted by Pyrrhus of Epirus. In 272 B.C., however, it was taken by the Romans and the conquest was repeated in 209, after the battle of Himara in the Second Punic War. It passed later under Byzantine sway, was destroyed by the Saracens.
TARANTULA — TARBEll

in 927 A.D. and later belonged to the Norman kingdom in South Italy. In 1861 it became included in the kingdom of Italy and the Italian government strongly fortified the place, establishing there a toa base. It is now one of the four important naval centres of Italy. Pop. about 56,000.

TARANTULA, a large spider (Lycosa tarantula) with a body about an inch in length; its bite was formerly supposed to produce a kind of frenzy in human subjects called tarantism. The nervous actions of those victims are supposed to be imitated in the wild musical dance known among the Italians as tarantella. Doubtless in some cases its bite produces disagreeable symptoms. The species named is a native of Italy, but varieties, or closely allied species, are found throughout the south of Europe. The so-called tarantulas of Texas and adjacent countries are large species of Mygale.

TARANTULA-KILLER, a very large burrowing wasp (Pompilus formosus) of Texas and Oklahoma, which stings tarantulas, depositing its eggs in their bodies and carrying the paralyzed spider off to its nest. See WASPS.

TARAPACA, tá-rá-pá-ká', Chile, a province in the northern part of the country, between Bolivia and the Pacific Ocean. Area, 16,000 square miles. The main range of the Andes is in the eastern boundary, while a lower range runs along the coast. The entire intervening country is a rainless desert traversed by a few streams in narrow valleys. The importance of the province lies in its immense deposits of nitrate of soda. These are found in the interior deserts and railroads are built from the coast to reach them. There are also some silver mines in the coast range. The capital and chief port is Iquique. The province was occupied by Chilean troops in 1879 and was ceded to Chile by Peru by the Treaty of Peace in 1883. Pop. 125,961.

TARASCO, an ancient tribe of American Indians which formerly spread over all of the Mexican states of Michoacan, in Guanajuato and Queretaro. The Tarascos have been called half-breeds in the Mexican population, but Lumholtz states that he came across the pure stock nearly 200,000 strong, in 1800, still living in the mountains of Michoacan. According to their traditions they must have come from the northern regions, as did the Nahua- thanes. They do not call themselves Tarascos but name their tribe Purépecha. In consequence of their absorption with other races their original customs, in most sections, are fast disappearing. They never mention the sun except as Our Father Sun and they transact no business nor will they sell corn after sun-down. They worshipped the Southern Cross constellation. In each house they place in the best room pictures of a saint or saints, which are said to be in the room, while the priest of reverence to the saint, sleep in the kitchen; but they allow strangers to occupy that room. The entire series of their saints is called Tata Dios, Father God. Capital incense is burned before their house daily, and the visitor, before mentioning the reason of his arrival, first kisses the saint's picture. The tribe has a great love for music and almost every individual has his guitar. They are hard workers, especially the women, who are badly treated. Like most Indian tribes, the Tarascos are clever potters. Consult Lumholtz, K. S. (Unknown Mexico) (New York 1902).

TARASCON, tá-rás-kón, France, a town in the department of Bouches-du-Rhône, on the left bank of the Rhône, opposite Beaucaire, with which it is connected by a suspension-bridge, 55 miles north-northwest of Marseilles. It is surrounded by walls, flanked with towers and entered by three gates. The streets are wide and regular and one of them is lined with arcades. The principal buildings are the old castle, seated on a height overlooking the river; the church, a handsome Gothic structure of the 11th century, with a finely sculptured portal; the town-house, courthouse, theatre, general hospital and public library. Woolen cloth, serge, silk goods, hempen and cotton cloth, vermicelli, soap, starch and cordage are manufactured and there are also brandy distilleries, wax refiners, tanneries, brickworks and building-yards for barges. The trade is wine, brandy, oil, hemp, wool, wood, coal, medicinal plants, lucerne-seed and saddles. Tarascon is the Roman Tarascon and in an interesting type of the medieval town. It is the locale of Daudet's 'Tartarin de Tarascon.' Pop. 8,631.

TARAXACIN, a crystallizable substance found by Pollex in the milky juice of the root of the ordinary dandelion. It is bitter and acrid in taste. Used somewhat as an alterative and tonic.

TARBEll, Edmund C., American artist: b. West Groton, Mass., 1862. He was a pupil in the Boston Museum of Fine Arts and going to Paris was taught by Boullanger and Legeb. In 1900 he took the Clark prize at the National Academy of Design; the Shaw Fund, Society of American Artists (1903); medal at the Columbian Exposition and other awards at Philadelphia, Boston and Paris (bronze medal 1900). In 1906 he was elected to the National Academy. For many years he has been art critic at the Boston Museum. His pictures are distinguished by fine atmosphere and color and the bold truthfulness of his outdoor work borders on impressionism.

TARBEll, Frank Bigelow, American archaeologist: h. Groton, Mass., 1 Jan. 1853. He was graduated at Yale in 1873 and was assistant professor of Greek and instructor of logic there 1884-87 and was instructor of Greek at Harvard University 1889-92. He has been professor of classical archaeology at the University of Chicago from 1894 and has published 'The Philippi of Demosthenes' (1880); 'A History of Greek Art' (1896); 'Catalogue of Bronzes, etc., in Field Museum of National History' (1899).

TARBEll, Ida Minerva, American biographer: h. Erie, Pa., 1941; Nov. 18. She was graduated from Allegheny College, Meadville, Pa.; was associate editor of The Chautauquan 1893-91; studied at the Sorbonne and College de France, 1891-94; from 1901 to 1906 was on the editorial staff of McClure's Magazine; is now associate editor of The American Magazine. Her publications include a 'Short Life of Napoleon

DIBU, tärd'ye, André Pierre Ga-
medée, French publicist and administra-
2 Sept. 1876. He passed out first in his
on the École Normale and entered the
tic service, being attached to the French
in Berlin in 1897. He served a while
Foreign Office and as a secretary in the
of the Council of Ministers 1899-
le was editor of the 'Revue des Deux-
and became foreign editor of the
He paid a visit to the United States
and recorded his impressions of that
in a French journal, and in 1904 in the
(1908). Of President Roosevelt, whom

he interviewed, he wrote then, 'What particu-
larly characterizes his policy is its essential and
emphatic Americanism,' an estimate corrobo-
ated by all Americans on the death of that
statesman 11 years later. M. Tardieu entered
in the general election preceding the out-
break of the war. He was made chief censor,
post he soon left for active service in the
rench. Incapacitated by a severe attack of
 pneumonia, brought on by exposure, he was
appointed head of the French mission to the
United States in 1917. He labored at
Washington and elsewhere for the business
iciency of the Allies and the co-ordination of
their economic strength. Returning to France
shortly after the formation of the Clemenceau
ministry, he later made another important trip
to America and subsequently remained in Paris
as high commissioner for all matters concern-
ing France and the United States. He was
the youngest delegate to the Peace Conference
In Paris. He wrote several excellent books on
European politics; his 'Questions diplomatiques
de l'année 1904' was 'crowned' by the
French Academy. A remarkable work is his
'Le Mystère d'Agadir,' dealing with Morocco
and Germany. He also wrote 'La Conférence
d'Algesiras' and 'France et les Alliances' (Paris
1907).

TARDIGRADA, tär'dë-gräd'a, a term in
zoology applied (1) to the group of sloths and
(2) to a group of microscopic animals also
known as water-bears, which are usually classed
with the Arachnida. The water-bears have a
cylindrical body bearing four pairs of short,
clawed feet, while the mouth is furnished
with two stylet-like rods. The nervous system
is much like that of annelids; circulatory
and respiratory organs are lacking. These
animals are hermaphrodite, and when the eggs are fer-
tilized the skin of the body is shed, the eggs
remaining in it. The development is more like
that of the annelids than like that of the
arachnids, and the relation of these animals to
the spiders is more than that of the fish relates
all live in fresh water, being common in
and fresh-water algae. Most of the species will
stand prolonged drying and will revive upon
being placed in water.

TARDIVEL, tär'dè-vél, Jules Paul, Ca-
adian journalist: b. Covington, Ky., 1851; d.
1905. He went to Canada in his 17th year and
was educated at Saint Hyacinth College. He
entered the service of 'La Minerve' and 'Le
Canadien' and (1881) established 'La Verité'
of Quebec, being its editor as well as proprietor
for a lengthy period. As a staunch Catholic he
propagated the creed in political matters, op-
posing liberalism and Freemasonry. He was
an advocate for entire independence of the
province of Quebec and secession from the
Canadian Confederation. He wrote 'La Vie du
Pape Pie IX, ses œuvres et ses douleurs' (1878);
'Notes de voyage' (1890); 'Pour le
patrie' (1895), a novel attacking Free-
masonry.

TARE, any of several plants. The tare
mentioned in the Bible (Matt. xiii, 25) is sup-
pposed to be darnel ('Lotium temulentum'),
since the Greek word 'Lotus' ("wild rice") is used in
the oldest Greek manuscripts. Darnel is distin-
ct from the wild rice and eating its seeds was for-
merly supposed to produce stupefaction. The modern tares are all members of the family *Papaveraceae*. The name is most commonly used for *Vicia sativa*, better known in England and America as the common vetch. This plant is cultivated to some extent in Europe because it will thrive upon poor soils and produce forage where other plants usually fail. Its yield is small, but in such places it is deemed worth while to be so used as a means of improving poor land. Its close relative, the wild vetch (*V. hirsuta*), also loosely called tare, is similarly named and used, but it is more often ranked as a weed.

**TARE,** in commercial technology, is an allowance for the outside packages of goods which cannot be packed without detriment, which is deducted from the weight if it be bought by the pound. Obviously the papers, threads, bands, etc., that enclose or hold any goods imported loose cannot be conveniently separated for weighing nor, in many cases, can casks or cases be weighed separately from their contents.

**TARENTUM,** ta-reno'tum, Pa., borough in Allegheny County, on the Allegheny River, and on the Pennsylvania and the Allegheny Valley railroads, about 20 miles northeast of Pittsburgh. It is in an agricultural and coal mining region. The chief manufacturing establishments are paper mills, glass factories, foundries, machine shops, flour mills and planing mills. It is a typical manufacturing town and its 65 factories turn out about $3,000,000 in products annually. There are banks and newspapers. The educational institutions are a public high school, public and parish elementary schools and a public library. Pop. 7,414.

**TARENTUM.** *See Taranto.*

**TARGUM,** the translation of the Old Testament Scriptures into Aramaic. This version originated at a time when Hebrew had given way to Aramaic as the popular language of the Jews. The need of explaining the old Scriptures to the people after their subjugation by the Persians is suggested by Nehemiah viii, 8, where we read that Ezra read the law to the people, while it was interpreted by his assistants, interpreters—Meturegans as they were called. As the Targum was not committed to writing, little of it has survived. There are indeed three Targums of the Pentateuch and of the Prophets, as well as of the Psalms, Job, Proverbs, the Song of Songs, Ruth, Lamentations, Esther and Ecclesiastes. The Targum is not of much critical value, but throws considerable light on the life of the Jews at the time it was composed. Consult Berlinger, A., *Targum Ontale* (Berlin 1854); Lacardere, *Propheète Chaldéen* (Leipzig 1872).

**TARIFF.** The taxation of goods by the imposition of customs duties upon passing the national boundary, is a special mode of raising revenue. The earliest form of this tax was probably the transit duty imposed on goods passing through a district and was justified as a payment for protection or for special facilities. The export duty levied on goods as they leave the taxing territory, came next in historical order. What in fact could be more just, it was thought, than a tax upon goods of whose use the home community would be deprived and the burden of which would be borne by the foreign consumer. Finally there developed import duties which are made use of in all civilized states to-day. Transit duties have disappeared as a form of national finance; export duties are of fiscal importance to-day only in Turkey and India. But import duties contribute a large though variable proportion of the revenues of the United States and of the leading European states. In the United States before the imposition of the income tax they made up nearly one-half of the Federal receipts; before the European War they constituted about one-half of the net receipts of the German Empire; about one-quarter of the total revenues of England; and about 15 per cent of those of France and Italy.

Among the civilized nations of antiquity tariffs for revenue purposes were generally used. The Greeks, and more especially the Athenians, levied customs duties upon both imports and exports, the usual rate being about 2 per cent. The Roman state levied regularly to this form of taxation. With the breakdown of centralized government during the Middle Ages the feudal lords claimed the right of imposing transit duties on goods passing through their domains, nominally in payment for protection. When feudalism in turn gave way to strong monarchies the rights of the lords in this regard were exercised by the kings and to local tariffs were added national ones. Every European country was covered with a network of customs lines which greatly hindered trade, but were not productive of commensurate revenues. The history of modern tariff legislation has been the simplification of this complicated system.

In England a complex system of import and export duties had slowly developed by the constant addition of new objects of taxation and by the confusing practice of assigning the proceeds of each new duty to a different purpose or fund. In 1787 Pitt consolidated all of the tariff duties into one general fund. At this time about 1,200 articles were subject to import duties and about 50 to export duties. The next step in the direction of simplification of the tariff was effected in 1824 by Huskisson, who abolished most of the export duties, freed raw materials of their burdens and consolidated a mass of tariff acts. The real beginning of modern English free trade was made during the period 1842-45, when some 9,816 articles were placed on the free list. Practically the only articles upon which import duties were collected after 1860 were sugar, cocoa, coffee, chicory, dried fruit, tea, tobacco, wine, beer and spirits. In spite of the decrease in the number of dutiable articles the revenues from the few remaining ones steadily increased, with a corresponding reduction in cost and simplification of administration. With the increasing competition of German and American manufacturers, especially since about 1900, a reaction in favor of protection has arisen in some quarters. Since the outbreak of the European War this movement has taken the form of a demand for protection for the colonies.

In France the diverse and multifarious provincial tariffs were swept away in 1790 and the following year a common and uniform tariff
foreign countries was established. For some time France had now economic unity. There were at first moderate, but under them they were highly protective, which was continued under the Resto
nd extended to agriculture as well as tures. Under the monarchy of Louis the government was administered in the same manner as high tariffs, duties, and costs were made highly protective, which was continued under the Restor
ital policy was introduced which cul
in the Commercial Treaty of 1860 with
. By 1881 the pendulum had swung their direction again, and the new tariff year was much more protective. A higher protection was extended to agricul
and since that time France has main
policies of all-around protection and self-sufficiency.
Its tariff policy has moved along different lines. At the beginning of the century the present German Empire group of mutually antagonistic states a few years ago when they were at war, at problem was to unite them under a regional tariff and to abolish the local e tariffs. This was finally accomplished under the leadership of Prussia by the Zoll
which continued from 1834 to the event of the German Empire in 1871, complete economic unity was effected. 1. Ifs under the Zollverein had been mod
now they moved still further in the direction of further tariff protection, but in 1878 a change
le to protection which has since been further, covering agriculture as well as manufactures. The tariff has been made more political as well as industrial and massive in Germany.
The United States customs duties have ed from the earliest colonial period. Every colonial assembly levied import or its own treasury in addition to those by Great Britain in the execution of Navigation Acts. They seemed to have been or sumptuary, retaliatory or protective, quite as much as for fiscal ends. Colonial tariffs have been classified under four heads: (1) tonnage taxes on shipping; (2) export duties on goods and other colonial staples; (3) im
ies on slaves; (4) regular tariff of goods. wines and liquors were the most it items. These duties were generally valued duties ranging from 1 to 5 ; but even with these rates seem to largely evaded.
Tonal tariff act was made possible by lation of the Constitution and the first legislation by Congress was the passage
y 1789 of such an act. The main pur
this was revenue, but protection was end to certain industries which it red to encourage, as glass and earthen
h the tariff rate of duty, however, was about 8 1/2 per cent, but in those days was a more effective barrier than it has been. No important changes were made
Act of 1816, but in the meantime the several tariff acts of those acts and the War which had interrupted foreign trade, ed into being manufactures of which now felt care should be taken. Ac

Accordingly this tariff act gave a substantial measure of protection to those industries most exposed to foreign competition, namely, textiles, hats, cabinet wares, flannel and calico. By 1824 other industries were demanding protection such as iron, wool, hemp, glass and lead and a general revision was made in the tariff, resulting in a raising of rates throughout the list but especially in the case of iron and steel. For the next few years there was continuous agitation of the tariff question, led by the woolen manufacturers who wished further protection. A convention of the friends of protection was held in Harrisburg in 1827 and systematic propaganda was carried on. The result was the tariff of 1828 which granted the highest protection yet accorded in any act, the chief beneficiaries being the cotton and woolen industries. This "tariff of abominations," as it was called, caused intense opposition both in the North and in the South, and it was replaced in 1832 by a more moderate act which eliminated the worst features of the previous tariff and put the duties back at about the point where they were in 1824.

The opposition of the South, however, was too great to be appeased by any half-way measures and in the next year it flamed out in nullification. South Carolina declared the Tariff Acts of 1828 and 1832 null and void and not binding upon the State or its citizens. In order to placate the opponents of protection and at the same time prevent too sudden and radical a revision of duties, Clay introduced the so-called Compromise "Tariff of 1833. This provided for a gradual reduction of all duties over 20 per cent to a 20 per cent level by an annual excision of one-tenth per cent until 1842 when they were all to be placed at that point. This agreement was carried out and the reductions took place according to schedule. Hardly had this been effected, however, than the protectionists seized upon the decline in revenues which had followed the panic of 1837 as an excuse for another revision of the tariff, and time in the direction of much higher duties; in general, the Act of 1842 returned to about the level of the Act of 1832. By 1846 good times had returned, there was a surplus in the treasury and a Democratic President and Congress were in office. They decided to make a radical change in the tariff policy which they enacted into law in the Act of 1846. This has often been called a free trade tariff, but it still retained a considerable protectionist flavor although the rates on the great bulk of commercial products were reduced to between 15 and 30 per cent. The next few years were years of unparalleled business prosperity and commercial expansion and the revenues from import duties increased by leaps and bounds. The need of a reduction of revenue was so obvious that in 1857 another tariff measure was enacted lowering many of the duties and enlarging the free list. Before this act was fairly in effect, however, the panic of 1857 put down importations to such an extent that a deficit resulted and accordingly in 1861 the previous duties were restored.

When the Civil War broke out the necessity for revenue outweighed all other considerations. Heavy excise duties were placed upon domestic manufactures and to compensate these the import duties were raised correspondingly.
and in some cases a little more. This was done in 1862, the average rate being raised to 37 per cent. The same procedure was followed again in 1864 except that a somewhat greater amount of protection was granted, the average rates being increased by this act to 47 per cent. After the war efforts to reduce the tariff to the ante-hellum basis met with resistance from the protected interests and practically nothing was done until 1870. In that year the duties on articles like tea, coffee, wine, sugar, molasses and spices, which did not affect domestic industries, were reduced. Again in 1872 a general revision was avoided by making a 10 per cent horizontal reduction of all duties and abolishing entirely those on tea and coffee and a few other articles. The loss of revenue resulting from the sacrifice of duties, amounting to about $20,000,000 from tea and coffee, and the shrinkage of other receipts as a result of the panic of 1873, resulted in a deficit of $2,000,000 and in 1875 the 10 per cent horizontal reduction was repealed. The period of depression came to an end about 1878 and with the return of prosperity a surplus began to heap up in the treasury again. In 1887 the public was granted power to propose changes, but their recommendations for a reduction of the tariff were rejected by Congress. Internal revenue duties were abolished or reduced, but the import duties were on the whole increased.

This action called forth strong protest from the Democrats, and in 1887 President Cleveland brought the issue to a head by a vigorous message urging tariff reform and the necessity of reducing the surplus. Up to this time the surplus revenues had been applied to the payment of the debt, but all available bonds had now been paid. The Democratic House passed the Mills bill providing for a general reduction of the tariff, but the Republican Senate replied by proposing further cuts in internal revenue duties. In the ensuing elections the Republicans were victorious and proceeded to solve the problem of the surplus by the double process of spending it and raising the import duties by the McKinley Act so as to accrue to the treasury. Extravagant protection legislation was inaugurated and a bounty of two cents a pound given to domestic sugar producers; at the same time imported sugar was admitted free, thus sacrificing an annual revenue of $30,000,000. These actions effectively removed the surplus and indeed paved the way for a deficit, which occurred when the panic of 1893 broke upon the country. The Democratic tariff of 1894 reduced the duties on many protected commodities, added to the free list, restored the duty on sugar and provided for an income tax. The failure of the income tax section, however, by being declared unconstitutional, and the continuing depression led to embarrassing deficits, and when the Republicans were returned to power in 1896 they promptly declared the passage of the Dawes-Tariff in 1897, raising the general average of duties to the highest point since the Civil War, namely, 57 per cent. This was an increase from 37 per cent in 1893 and 49.5 per cent in 1895.

The tariff now remained undisturbed for 12 years, but dissatisfaction with the existing duties grew strong, especially with the burdens on raw materials and the favors to monopolized industries. Efforts were made within the Republican party itself, especially by members representing the Middle West, to secure a revision of those duties favorable to the farmers, although without success, but finally in 1909 a campaign pledge was made by this party to revise the tariff. The Payne-Aldrich Tariff of 1909 was an attempt to redeem this pledge, but the protective interests united in preventing any serious reductions in schedules. This repudiation of party pledges led to an insurgent movement which found expression in the Progressive party and swept the Democrats into power at the next election. The Underwood Tariff of 1913 made important changes, especially in the iron and steel schedules; free wool was provided for, a gradual reduction of the sugar duty with ultimate free sugar, and the general free raw materials were manufactures. The outbreak of the European War the following year necessitated the suspension of the reduction of sugar duties, thus saving a revenue of some $45,000,000 a year. The enormous revenues needed to defray our expenditures since the entry of the United States into the war have been provided, as in the case of the Spanish War in 1898, by increasing the internal revenue taxes and by income, inheritance and excess profits taxes. An expert tariff commission was provided for by the Tariff Act of 8 Sept. 1916, which it is expected will supply the machinery and the information for the scientific solution of the difficult problems of tariff adjustment after the war.

ERNST L. BOSGART,
Professor of Economics, University of Illinois

TARIFF ADMINISTRATION IN THE UNITED STATES. The administration of the tariff laws, which comes within the province of the Treasury Department, is directed under the care of the Secretary of the Treasury and one of his assistant secretaries. The machinery furnished by the department and the government for its execution is comprehensive, complicated and far-reaching. All articles imported must follow a certain prescribed and unchangeable routine which begins with the requirement of a certificate of value made before a United States consular office abroad, for every shipment of foreign merchandise destined for entry into the United States. The exact methods of entry of goods, the valuation of the same, their classification and the rate of duties to be paid, in each case, are minutely and exhaustively prescribed; and provision is made for appeal of the interpretation of the Tariff Law, the classification of articles, the tariff charges or duties and, in fact,
er injustice or irregularity that may connection with the administration of . This system of appeal is very elabo-
i is at the service of the importers government alike. Naturally the tariff
tation takes charge of the collection of the import duties. It does directly notwithstanding that the extent and importance of the port cities would seem not only to justify

IFL LAWS, the various enactments of
; extending from 1789 to 1913, to regu-
ort duties. Those of recent date are:
The Morrill Tariff Act (1861); McKinley Tariff
Act (1890); Wilson-Gorman Tariff (1894); Dingley Tariff Act (1897); Payne-Aldrich
Tariff Act (1909); Underwood Tariff Act (1913). See TARIFF ADMINISTRATION IN THE
UNITED STATES.

TARIJA, tā-rē'kō' Bolivia, the capital of
the department of the same name, situated
among the mountains near the Argentine fron-
tier and having an area of 31,567 square miles.
It lies on a fertile mountain plain and has a
pleasant climate. The town has a handsome
church, and there is considerable transit trade
with Argentina. Pop. of town, about 10,000;
department, about 165,000.

TARIM, tā-rēm', central Asia, a river of
East Turkestan, formed by the confluence of
the Aksu, Yarkand and Khotan-Darya at the
southern base of the western Tyan-Shan
ranges, 60 miles southeast of Aksu. Thence
it flows east and finally southeast, losing itself
in the group of lakes and salt marshes known as
Lob-nor, at the northern base of the Kuen-Lun
range. With its main headstream, the
Yarkand, the Tarim River encircles the vast des-
cert plain of Turkestan, receiving nearly all its
tributaries from the surrounding mountains on
its left bank. The Tarim and its basin were
first thoroughly explored and mapped by Hedin,
during the last years of the 19th century.

TARKINGTON, (Newton) Booth, American
novelist: b. Indiana, 29 July 1869. He was
graduated from Princeton in 1893 and his first
novel, 'The Gentleman from Indiana' (1899),
attracted widespread and favorable attention.
Thenceforth he followed literature, with the
exception of serving one term in the Indiana
legislature in 1903. His next works were
'Monsieur Beaucaire' (1900); 'The Two
Vanrevels' (1902); 'Cherry' (1903); 'The Beau-
tiful Lady' (1905); 'The Conquest of Canaan'
(1905); 'Gust of Quesmay' (1908); 'Beauty
and the Jaquot' (1911); 'The Art' (1912);
'Penrod' (1914); 'Seventeen' (1916); 'Tur-
mol' (1917); 'Robert Cortes Holiday'
(1918); 'The Magnificent Ambersons' (1918).
He has also written several plays, the most
successful being 'Monsieur Beaucaire' (after
the novel), in which he collaborated with
Harry L. Wilson.

TARKIO (tār'kē-ō) COLLEGE, located at
Tarkio, Mo. It was established by private
initiative in 1883 under the name of Tarkio
Valley College and Normal Institute. A new
charter was obtained in 1884 by which the name
was changed to Tarkio College and the institu-
tion came under the control of the United
Presbyterian Church. The college has from
the first coeducational. Its organization
includes a collegiate department, a normal
department, a preparatory department, a tech-
ical department and a commercial department.
The collegiate department offers two courses
leading to a degree, the classical (degree of
A.B.), and the scientific (B.S.), and a third
course, the literary, for the completion of
which a diploma is granted; this latter
omits one year of the work of the scientific
course. The normal course occupies four years; stu-
dents are allowed to pursue the studies they
most need. Students in both this and the com-
mmercial department can take additional studies in any of the collegiate courses. Bible study is a part of the curriculum in the preparatory and collegiate courses. The college has a campus of 20 acres a little above the town; the chief buildings are the main building, Marshall Hall (women's dormitory) and Gentleman's Hall. In 1901 David Rankin gave $53,000 toward the increase of the permanent endowment, and the productive funds were in 1917 $163,000. The library in 1917 contained 8,300 volumes; the students numbered 235 and the faculty 23.

TARLAC, tār'lāk, Philippines, (1) Pueblo, capital of the province of Tarlac, Luzon, on the Bolso River at the point where its name changes to Tarlac, and on the Manila and Dagupan Railroad, 73 miles northwest of Manila. In addition to the railroad it has excellent highway facilities, and is the centre of trade for the surrounding country. Pop. 12,340.

An interior province in the southwestern part of northern Luzon, bounded on the north by Pangasinan, on the east by Nueva Ecija, on the south by Pampanga and on the west by Zambales. Area, 1,715 square miles; altitude, approximately square, measuring 37 miles from north to south and 39 miles from east to west; the eastern part is level, while the western part includes the eastern slopes of the Cordillera de Calusacan, the highest peak being Mount Ha, 1,004 feet. The province is watered by numerous rivers. Rice is the most important product; sugar is also raised in large quantities, and tobacco and corn on the higher levels. The forests are valuable, and the timber is easily obtained on account of the numerous rivers, and their proximity to the forest lands. There are a few mechanical industries for domestic use only. The province is traversed by the Manila and Dagupan Railroad, the main highways and numerous lesser roads; the rivers also are navigable for native boats, so that the facilities for trade are excellent. Pop. about 135,000.

TARLATAN, a thin and fine species of open, transparent muslin, mostly used for women's wear, originally esteemed as high grade, but later deteriorated. The chief seat of the trade is Calcutta.

TARLETON, Sir Banastre, English soldier in the Revolution; b. Liverpool, 1754; d. Leintwardine, Shropshire, 25 Jan. 1833. In 1775 he entered the English army as cornet in the king's dragoon guards, and obtained leave to accompany Lord Cornwallis to North America, as volunteer. He was present with Clinton's army at the attack on Charleston and other operations, then served with Sir William Erskine's cavalry, attacking and capturing New York (September 1776), Fort Washington and Fort Lee in November. He commanded the advance guard under Haerquert and captured General Lee (13 December) and was present in operations around Brunswick, Princeton and Trenton (1777). In 1780 he fought around Charleston capturing (by surprise) three regiments of American cavalry, with their stores, just before the capitulation of Charleston. He aided in the capture of Camden. In the South he had to retreat, after Morgan's victory at Cowpens, in Hamilton Ford. Joining Leslie in January 1780 they returned and successfully attacked Morgan. But in spite of Tarleton's numerous successes the attacks of Lafayette and Wayne rendered the Cornwallis position hopeless and, with the surrender to Washington, Tarleton returned to England (1782) on parole. He was made lieutenant-colonel of light dragoons in December, the new reorganized Parliament (1780) representing Liverpool, retaining his seat till 1807. In 1807 he was again elected to sit till 1812, giving his seat to Canning. He was promoted (1790) to colonel, then to major-general (1794) and lieutenant-general (1798). After several short commissions to Ireland and elsewhere he was made (1818) governor of Berwick and Holy Island. In 1812 he was promoted to general and was created baronet in 1815. He was certainly a clever, daring and successful leader of cavalry, but history would give him the blame for unnecessary cruelty, resorting at times to butchery. He wrote 'History of the Campaigns of 1790 and 1791 in the Southern Provinces of North America' (London 1797).

TARN, tārn (ancient Tarnis), a river of France, which rises on the south slope of Mount Lozère, near Florac, in the department of Lozère. It flows west-southwest, crosses the departments of Aveyron and Tarn, passing Alby, turns northwest through Haute-Garonne into Tarn-et-Garonne, where it passes Montauban, turning almost due west, passes Moissac, and joins the Garonne on the right a few miles below. Its whole course is 230 miles, of which about 100 miles, beginning at Alby, are navigable.

TARNOPOL, tān'pōl, Austria, town Galicia, on the left bank of the Sereth, 80 east-southeast of Lemberg, near the Russian border. It has a Roman Catholic and a Greek Catholic church, an old castle, now used as barracks, a new castle, a Jesuit college, a gymnasium, a Polish real-school and several of schools. A thriving trade in refining and brewing, horses, grain, wax, honey, etc., is carried on. Pop. about 35,200.

TARO, a plant (Colocasia antiquorum esculenta and related forms) of the arum family, widely grown for food in tropical regions, especially in the Islands of the South Pacific. The plant has very large heart-shaped leaves, from thick tuberous roots, and small greenish flowers, resembling those of the calla, to which it is related. A form, still grown in Egypt and used as food by the laboring classes, is known to be of great antiquity. In the Pacific region hundreds of forms of taro are recognized by the natives. Taro is used in Hawaii chiefly in the form of poi, a paste made by boiling and grinding the roots and allowing them to ferment for a day of two. The roots are used in many other ways, like the potato. The leaves, also, when cooked to destroy their acridity, are used for food.

TARPAN, a local name for the Asiatic wild ass.

TARPAULIN, originally a broad piece of canvas, thoroughly coated with tar, and used to cover the hatchways of a ship at sea, to prevent the penetration of the rain or seawater which may at times rush over the decks; now any heavy waterproof canvas for protecting goods from water.
TARPEIAN ROCK—TARQUINIUS

TARPEIAN (tär-pé'yán) ROCK, Italy, a
hill at the Capitol at Rome, so named from
legend that during a war with the Sa-
arpeia, the daughter of the governor
of Rome, promised to open the
the city to the Sabines, provided they
what they carried on their left hands,
the Sabine public to the Capitol,
d, and as they entered the gates threw
bracelets but their shields upon Tar-
io was crushed to death under the
She was buried in the Capitol, which
named the Tarpeian Rock; and
Roman malefactors were afterward
down a deep precipice. See ROME.

PON, or SILVER KING, a great
erful fish (Tarpon atlanticus, or Megal-
azaoides), known from Virginia to
and regarded by anglers as the finest
American game fish. It is related to the
and resembles them in general out-
is sometimes six feet long. Its special
the long filamentous appendage of the
margin of the dorsal fin and the
und, which is used as the
in armor of glittering silver, and make
silver king peculiarly appropriate
noble fish. Among the French and
fishermen about the Gulf of Mexico
berg. It is called grande escotte,
valle, etc., while tarpion, jewfish and
herring are also heard. Its scales, as
or larger than a silver dollar, are ex-
used in fabricating ornaments, and the
food to eat; but the fish is principally
for the sport it affords to the angler
line, who seeks it best by going
, with an experienced man at the oars,

TARQUINIUS, Lucius (surnamed Su-
PERBUS), last of the legendary kings of Rome,
was the son of Lucius Tarquinius Priscus.
Tarquinius Priscus left two sons, who were
himself too young to succeed him in the
his son-in-law, Servius Tullius, excited the patricians
against him by extensive constitutional reforms,
and Tarquin, on reaching man's estate,
murdered his son-in-law and assumed the regal
dignity as a hereditary right. As a king he
developed all the distinguishing traits of a
tyrant. He abolished the privileges conferred
by his predecessor on the plebeians; but did not
favor the patricians. He banished or put to
death the senators whom he suspected. He
continued the great works of his father,
compelled the populace to labor in the
for inadequate pay. While he thus established
his tyranny at home he advanced the power of
Rome abroad. By the marriage of his daughter
Octavia Mamilius of Tuscum, he
caused himself to be recognized as the head of
the Latin confederacy. Through a stratagem
of his son Sextus he obtained possession of
Gabin, a Latin city, which resisted him. He
made war on the Volscians, and took the city
of Suessa Pometeria, the spoils of which he
used to build and decorate the Capitol. He
formed also a close alliance with the Etrurian
cities. To keep down the Volscians, he founded
the colonies of Signia and Circeo. It was he
who deposited the Sibyline books in the vault
of the Capitol. After a reign of nearly 25
years he was engaged in besieging Ardea when
the conspiracy broke out by which he was
exiled from Rome 510 B.C. The cause and nature
of the conspiracy are referred to in the articles
BRUTUS (LUCIUS JUNIUS) and LUCRETIA. Tar-
quins first took refuge at Cerc and Etruria. The
Etruscan cities of Tarquinius and Veii first
espoused his cause, then Lars Porsenna of
Clusium, and afterward the Latin states.
When all these had been vanquished, according
to Roman accounts, Tarquinius, whose sons had
perished in the wars, fled to Cumae, where he
died. The chronology of the story of the Tar-
quins is incompatible with strict historical
accuracy, and neither contemporary
public statements nor a mass of accounts has enabled historians to disentangle
the truth from fiction. Some, as Niebuhr and
K. O. Müller, hold that the history of the Tar-
quins points to an Etruscan conquest of Rome.
Others accept the main incidents as historical.
TARR, Ralph Stockman, American geologist: b. Gloucester, Mass., 15 Jan. 1864; d. 1912. He was graduated from Harvard in 1891, and was assistant in geology there 1890-91. From 1892-97 he was assistant in geology at Cornell University, and thereafter at dynamic geology there until his demise. He has published 'Economic Geology of the United States' (1893); 'Elementary Physical Geography' (1895); 'Elementary Geology' (1897); 'Physical Geology' (N.Y. 1902); 'Geography of Science' (1905); 'Alaskan Glacier Studies' (1914); 'College Physiography' (1914).

TARRAGON, a culinary herb. See Artenisia.

TARRAGONA, tár-rá-go'ná, Spain, a seaport town on the Mediterranean, capital of a province of the same name, in Catalonia, 60 miles west-southwest of Barcelona, at the eastern end of the fertile Campo de Tarragona, which is watered by the river Francoli. The old town, situated on a high rocky site, once surmounted by a citadel, has irregular streets. The chief features are the splendid cathedral and the tower, with a fine west facade and cloisters of great beauty, the archiepiscopal palace, with an ancient tower, and a seminary for priests. The Plaza de la Fuente, on the site of the Roman Circus, separates the old town from the more regular new town to the southwest, which, near where it joins the old town, is crossed by two broad tree-shaded streets. The Paseo de Santa Clara is a fine promenade on the remains of the old Roman walls. The other edifices include the preside or prison, the Torreón de Pilatos, also a prison, the Casa Provincial de Beneficencia, artillery arsenal, infantry barracks, etc. The town and its neighborhood are rich in Roman remains. The spacious harbor is sheltered by a long mole, and has been recently improved. Tarragona was known to the Romans as Tarraco. It was captured by the Romans 218 B.C. during the Second Punic War, and made their headquarters in Spain. It is also called Tarraco Maior, that is to say, Tarraco maior, the latter of whom made it the capital of the province of Hispania Tarraconensis. It was taken by the Visigoths in 475 A.D., and by the Moors in 713. On 29 June 1811 it was captured and plundered by the French under Suchet. Its archbishop shares with the archbishop of Toledo the title of primate of Spain. Pop. town, 24,548; province, 336,763.

TARRYTOWN (from the Dutch, Terwegen Dorp, "Wheat Town"), N. Y., village, Westchester County, on the Hudson River, or the expansion of the river called Tappan Zee, and on New York Central and Hudson River Railroad, about 25 miles north of New York and 100 miles south of Albany. A ferry, which connects the village with Nyack on the west bank of the Hudson, gives Tarrytown the advantage of the water. Tarrytown is one of the oldest settlements in New York; its position on the Hudson made it a convenient landing place for boats going from New York to Albany, and gradually it became a trading post. Its first incorporation included Irvington (1817). During the Revolutionary War Tarrytown was a centre of importance; every prominent hill in the vicinity was scene of an encounter or a fortification. Tarrytown André was captured. On Br one of the prominent streets, about half Sleepy Hollow (q.v.) stands a monument memorating the spot so important to Independence. The first monument was a small obelisk, raised in 1853 by inhabitants of the county, and bearing a pedestal an inscription which told that it is the "spot" where St. John Andre was captured by Paulding, Davila Williams, and Isaac Van All Natives of this County. In 1880, the centennial anniversary of this capture, the added a bronze statue of John Paulding; bronze panel, upon which was picture Theodore Bauer, the capture of André additions of 1880 were the gift of John son. The little stream nearby is called Brook, and a large whitewood, which stood near the monument, was called the tree. In 1777 Vaughan's troops landed and here, at the tavern kept by Elizabeth Tassell, occurred the capture of the Bri Major Hunt and a force of volunteers. The village is well laid out, and is the birthplace and home of Washington (q.v.). On the north is Sleepy Hollow where he was buried, on the south is Tappan Zee (q.v.), where his home stands. Other porion of Tarrytown include "Lyndhurst," formerly "Paulding Manor", Philipse manor house, erected in 1663; a monument to the Revolutionary soldiers manor, unveiled in 1894; and the sumptuaries of many of the noted men of New Tarrytown is in an agricultural region has about 100 manufacturing establi with a large annual output. The principal buildings are the Institution of Me orphanage for boys; the churches, scho business and schools. The educational insti are the Washington Irving High School, Institute, Miss C. E. Mason's Scho Knox School, Hackley School, Mary School, public and parochial schools, three libraries and two academies. The national bank has a capital of $100,000, it ing bank has deposits amounting to $2,000,000. Pop. about 5,752; including Tarrytown, 4,877; which is industrially of the village; total, 10,629.

TARSHISH, a place frequently men in the Old Testament. It was formerly believed to be Tarshish in Sicily, but is nonlinearly identified by Biblical critics with Tartessus of the Greek and Roman This name was applied to a district in the of Spain, lying to the west of the Gulf of Hercules. Others regard it as some tified European coast west of Greece.

TARSHA (Ital. Intarsia). Wood especially that done in Italy at the close Middle Ages and during the era of the Renaissance. The word is recorded being the only one describing inlay of character as distinguished from o others. Thus nearly all Tarsha work in dark wood like walnut, on which the lines and curves are incised rather dee the incisions then filled with light colors, producing, when the work is complete, a
vellow on brown. These lines and scrolls of different patterns which are carved in caps of foli, in this way help to carry out the great arabesque decoration which we, associate with the Renaissance proper in all the schools.

Heavy furniture, such as cupboards, chests, and monk beds for the storing of books, and the like, are adorned in this the most effective examples of the art of wooden fittings of church choirs and rows of cupboards and closets (am-buch) line some of the sacries of the in central and northern Italy.

Inlay of later times and of the North often called Tarsia, but the process is of the style of the time. The most wood inlay of Italy is that of chests of drawers, wardrobe and tables in which spirited little bouquets of flowers are relied on a dark ground. All northern inlaid work, disappear in century in what we call Marquetry which is a mosaic of veneers rather inlay. Consult Jackson, F. Hamilton, and Marquetry (1903).

SIER, a small emer of the genus having extremely long hind legs, es-n in the thin tarsal portion, large, slender, enormous eyes. These grotesque little organisms inhabit tropical Africa and the East African islands. They are for the most part rai with orchids and feed on roots and in- nents in the trees near them spending their life in these spots where they spend a. The tarsier (F. spectrum) is a rep- ve species of this genus, occurring in Celebes, the Philippine Islands, etc. It is brown, with olive tints over the body, tints on the face, forehead and back sad. The tail is destitute of hairs, but a tuft at its tip.

SUS, Asia Minor, an ancient city, the capital of the Roman province of the same name, is now in the Turkish province of Adana and of the Mediterranean. It was once adorned by a number of magnificent buildings. Its inhabitants enjoyed the privileges of Roman citizens, and the city rose to inaction as a rival Athens, Antioch and Rome in wealth and grandeur, as well as in arts and sciences. It is the birthplace of Julius Caesar. It was situated on both banks of the Euphrates, which flowed into a lagoon con-tinental in the sea, which formed its port, and later, a harbor. Its origin is ascribed to Sar.-etas. It was early colonized by the Phoenicians, and it is thought to have been a great and wealthy city. Tarsus was colonized by Cyrus in his expedition against the Persians, and partially plundered by the Gauls. It yielded to the absence of the empire of the Seleucid, but was of the same state with Egypt under the Ptolemies. Pompey made Cilicia a province. Out of compliment to the Seleucids by gift of its name to Julii. It was plun-

TARTUS (in anatomy). See Anatomy; Foot; Osteology.

TARTAGLIA, tär-tal-yā, Nicola, Italian mathematician: b. Brescia, about 1500; d. Venice, 13 Dec. 1557. His family name was Fontana and he was given the name of Tartaglia, the stutterer, from a defect of utterance contracted during his neglected childhood. From the year 1530 he taught mathematics at Verona and Vicenza, was appointed professor of mathematics at Brescia and in 1534 was called to the same post in Venice. He discovered the method of solving the cubic equation containing the 1st, and 3d powers of the unknown quantity, and in repeated contests with the ablest mathematicians of his time defeated them and was able to solve all their problems, while his own remained unsolved. In 1539 and 1540 Cardan, under the promise of strict secrecy, obtained from him his discovery, and afterward, in violation of his promise, published it in his Ars Magna. This led to a violent controversy and a public mathematical contest, in which Cardan was worsted, his townspeople raised a mob and prevented a continuance of it. But the solution is still known as Cardan's rule. His chief work is 'Generale trattato de' numeri et misure' (1556). He also published a treatise on gunnery, 'Novella Scienza,' which has been translated into English by Lucear; the first Italian translation of Euclid; and seven or eight other mathematical works, the best known of which is 'Questi ed invenzioni diversi' (1559).

TARTAN, the typical Scottish plaid; a thin worsted cloth having alternate bands of different colors, forming a checkered pattern, which has been highly specialized by Scotch weavers for the dress of the Scotch Highlanders, each clan having its own peculiar pattern. The well-known Stewart tartan is scarlet in the centres, with dark blue, green, and white lines and wide-spaced dark independent lines. An endless variety of fancy tartans are now manufactured, some of wool, others of silk or mixed material. The term is also applied to the checkered patterns themselves.

TARTAR. See Arbol.

TARTARAGA, a South American turtle of the family Pelomedusidae; specifically the great "arru" or river-turtle (Podocnemis expansa) of the Amazon Basin, the female of which has a shell sometimes measuring three feet in length. This turtle is of great commercial importance throughout northern South America, on account of the eggs, which are periodically collected from the sand banks where they are buried by the river, chiefly for the oil to be pressed from them. This is either eaten, like the eggs themselves, or is burned in lamps alone or mixed with tar. The turtles are likewise eaten by man and many animals.
TARTARIC ACID—TARTARIN

TARTARIC ACID, Dihydroxysuccinic
CHOHCOOH
Acid, | exists in four stereoisom-  
CHOHCOOH
eric modifications; these are known as (1)  
Dextrotaartaric acid, or Ordinary tartaric acid,  
(2) Levotartaric acid, (3) Racemic acid and  
(4) Mesotartaric acid.

1. Dextrotaartaric Acid and some of its  
salts are widely distributed in the vegetable  
kingdom, its acid potassium salt being present  
in large quantities in grape juice. When grape  
juice is fermented, the acid salt, being only  
sparingly soluble in the alcohol produced, forms  
a dirty-white crust or sediment in the fermenta-  
tion casks; this deposit is known as "argol" or  
"lees." Cream of tartar and ordinary tartaric  
acid are usually obtained from this source.  
For the preparation of cream of tartar, argol  
is simply freed from impurities by treatment  
with animal charcoal and by subsequent crys-  
tallization. For the manufacture of ordinary  
tartaric acid, argol is boiled with dilute hydrox-  
ed potassium acetate, and then precipitated as calcium  
tartarate with calcium hydroxide. The yield  
is increased by adding calcium chloride to the  
mother-liquor. From the calcium salt thus pre-  
cipitated tartaric acid is liberated with dilute  
sulphuric acid.
A number of synthetic methods are also  
in common use for the manufacture of tartaric  
acid. According to British Patent 12,467, the  
compound may be obtained by the elec-  
trolytic reduction of glyoxylic acid or its  
deuterated glyoxylic acid and then precipitated  
as calcium tartarate with calcium hydroxide.  
The yield is increased by forming oxalic acid  
by the action of amalgams. The method of  
L. Baeckeland (United States Patent 1,190,845)  
consists in building up the acid from the oxides  
of carbon by converting them into formates;  
from these, oxalates are obtained at high  
temperatures and pressures; the oxalates are  
reduced to glyoxylates, and the latter electrolyzed  
to tartarates. Tartaric acid has also been  
obtained by the oxidation of carbohydrates in  
the presence of catalyzers (British 108,494).

Dextrotaartaric acid crystallizes in trans-  
parent prisms, free from water of crystallization.  
It melts at 170° C.; above this temperature  
it yields pyrotaartaric acid, acetone,  
acetamide and other decomposition products.  
It is very soluble in water and alcohol, but  
insoluble in ether. In aqueous solution it turns  
the plane of polarization to the right, reduces  
ammoniacal silver compounds, is readily de-  
composed into glyoxal and other products in  
the presence of uranium salts, and yields large  
quantities of carbonic acid and acetamide  
in the presence of mancanese dioxide at or above  
35° C. Under the influence of ultra-violet rays  
tartaric acid evolves carbon dioxide. The  
crystals of the acid show triboluminescence.  
In the form of its acid potassium salt the com-  
 pound has been used by the ancients. The pure  
acid was first described by Scheele in 1769.

2. Levotartaric Acid differs from the dext-  
roatartaric in that it turns the plane of polarization  
to the left. It was first prepared by Pasteur from sodium  
ammonium racemate. When this salt is allowed  
to crystallize it deposits two sets of crystals from  
which dextrotaartaric and levotartaric acids may be  
obtained. Pasteur's observations showed in-  
"Tartarin de Ty" (1872), "Tartarin sur les Alpes" (  
"Port-Tarascò" (1890) present Daudet  
remembered characterization, a typical Provençal  
man of the Midi, such as he has been described in speaking of his other novels of the South, Numa Roumestan: "...the theatrical, living parade, costume, situation, colour, blazing, triumphant, emotional, caressing, feline, with an eloquent, excited yet colorless, quick to yet giving anger a sham expression even if it is sincere." Looking back on in the years that followed since, it occurred to me that "Tartarin" has qualities of vitality, truth,—a truth from over that may swell and exaggerate facts, really lies."
This presentation of "truth from humorous side," in the phrase of Daudet's
TARTARS—TARTE

TARTE. See Tatars.

TARTARUS, târ-târ'ûs, according to classical antiquity, a deep pit which extends under the surface of the earth as completely as heaven extends over it, holding within closed portals Kronos and the Titans in their punishment. It was the jail established by the mythical gods for those whom they had driven from the supernal world, just as Erebus was a similar prison for men. Later the term came to signify the whole underworld in which the wicked undergo the punishment of their crimes, the exact opposite to the Elysian fields, the afterworld of the good. Tartarus, as a personification, is the son of Æther and Ge (air and land), and father of the giant Typhoeus by his own mother, Ge. 

TARTARY, târ'târ, or TATARY, a name applied in the Middle Ages to the countries from which the Tartars came or in which they lived, that is, central Asia and what is now southeastern Russia, western and eastern Turkestan, Mongolia and Manchuria. In a narrower sense it includes only southeast Russia and Chinese Turkestan.

TARTE, târt, Joseph Israel, Canadian statesman: b. Lanoraie, Quebec, 11 Jan. 1848; d. 1909. He was educated at L’Assumption College, was a member of the Quebec assem-

TARTARS. Zola, developed out of observa-

tions of the Midibô from the subtle

effects of Gascon temperament in 1872.

The

was begun in 1868, but this "cinematographic" first showed its sublunary atmosphere of the Rimbaud's self-deception. "Of a man who had lived going unhappily in one of the few who had been there,"

In his favorite reading of the local color for the self-deception of his own life, he became the victim of the false sense of identity with his fellow-men. The Quixote in him says exclaimed: "I go!" the Sancho: "I go!" Tartarin cover yourself with glory!" Quixote. "Cover yourself with filth and mud, Tartarin, who dreamed of daring deeds in lands, till he was 45 had never slept his own home town. The Quixote in him says: "Give me a toma-

nacho. A lion seen at a circus fires his sails all the way. He must go to Africa to attain his self-esteem and reputation at Elaborate preparations keep his fantasy real till he sets out for Algeria. And disillusion follow, in amusing such his landing in exotic equipment among Europeanized denizens of Algiers. Tartarin's animal propensities for a he shoots a donkey for a lion, where are the customary game, beguiles him. Tartarin is beguiled with Oriental pleasures, is to his Quixotic self by a paragraph in jest. In his face resolutely south-

counters a tame and blind lion, imagines fired at another, is robbed by his com-

an alleged prince, shoots the tame lion burns with a melancholy camel, whom he abandoned to his own fate, and who re-

stay lost, much poorer in purse but earned the privilege of dazzling his fel-

men with tales that he, confirmed by 1 of the tame lion, himself half believes are.

ends this delightful bit of Provencal ge. Often, as obvious, it graces the me, but is always saved with unfailing me more buffoonery. In Tartarin on s' the spirit and method are the same, it is all a little mellower and more It is reinforced by the Midibô's more readily appreciated, as he is more generally familiar. The public critics join in pronouncing it the piece of French humor in the 19th cen-

The opening scene where Tartarin, equipped as for the Himalayas with ice-axe, climbing irons, snow-glasses and the rest, makes his entry into the patrician hotel on the Rigi, with its 600 very prosaic tourists, is unforgettable; so, too, is the tale of Tartarin's hunt of the tame chamois, trained to attract strangers and fed in the hotel kitchen. The Swiss Exploitation Trust, created in the spirit of the en-
ily in 1877-81 and was returned to the Canadian Parliament for Montmorency in 1890. He was again re-elected in 1891, as a result of his insistent attacks in the administration of Macdonald, whose ministers he charged with corruption, but in 1893-96 was member for L'Islet. He was later, under the Laurier administration, Minister of Public Works, and his editions at Montreal, Le Cultivateur, and La Patrie.

TARTUFE, a comedy of Molière in five acts in rhymed verse, the first three acts of which were presented for the first time before the king and queen at Versailles, 12 May 1664, when the author was 38 years old. The play made enemies everywhere. There were those among the Jansenists and Jesuits who each thought that the others were aimed at, and a violent attack was written by the curate Pierre Rouillé under the title Le Roy glorieux et menteur (Paris 1664), which upon Molière's protest was censured by the king. The latter nevertheless forbade the play to be presented again until finished. On 5 Aug. 1667, a second version of the play was presented at the Palais Royal under the title L'Imposteur. Molière, apparently upon the suggestion of the papal legate and his entourage, had softened it in several respects; for instance, the original Tartuffe was no longer in ecclesiastical garb. Nevertheless, its presentation was stopped, in the king's absence, by the first president of Parliament and interdicted by the archbishop of Paris. The king, despite his prohibition, had shown his favor by taking Molière's players under his patronage in 1665. It was only on 3 Feb. 1669, however, that a third version, the only one known to us now, was acted at the Palais Royal by the king's permission under the original title, and the poet's long years of waiting for a hearing were rewarded by extraordinary success. The plot of the play, which is masterly in its simplicity and logic, concerns the entrance of one Tartuffe (or Tartufe or Tartuffe), a self-seeking adventurer hiding his greed behind the mask of piety, into the house of Orgon, a well-to-do landowner. Orgon, who has been affianced to Valère, Orgon (played by Molière) and his opinionated old mother, Madame Pernelle, fall completely under the sway of Tartuffe over the protest of the rest of the family, including a rather hot-headed son, Damis, and a sensible and even-tempered brother-in-law, Cléante. Orgon goes even so far as to make a deed of gift to Tartuffe and to promise his daughter to him, despite a previous promise to Valère. It was not on the daughter, however, but on Orgon's second wife, Elmire, young and comely, that Tartuffe had cast longing eyes. To save her step-children, Elmire (played by Molière's wife) consents to lure Tartuffe into an avowal which her husband may overhear. This scheme being successful, the impostor throws off the mask and impudently claims the house under the deed of gift. Orgon's ruin is narrowly averted by the intervention of Louis XIV, a very evident device to which Molière restored the house to Orgon and hales the villain off to prison. It is not only for the singularity and boldness of the subject or the skill in which it is treated that this play merits approval. The first scene is as it is new, as full of simplicity as it is bold, and so commonly made use of in old grandmother, offended at what amiss in her granddaughter, is inflicting a severe lecture to those who blame her house, in which she draws the censure from all; for we distinguish through the language of prejudice this moment everything is in motion. Actually it gradually increases to the end. The coolness of Dorine (played by Marie Martin), a maid, in the scene with Tartuffe gives us a clear view of Orgon and his devotion. Tartuffe, who is only an actor in the first two acts, makes his appearance in the third, when the plot being so animated receives equal vivacity. The schemes employed against this villain are the address with which he turns away. The infatuation of Orgon, which in proportion to the title L'Imposteur was given occasion to that singular and singularly acted scene of the fourth act, which the perfect unmasking of a vice so abominable as that of hypocrisy renders indispensable. The sarcasm of Louis XIV, put in the mouth of the character of Tartuffe, exempt at the end of the play, could not be faulted by the unravelling in the eyes of the critics. Here indeed is the insuperable defect. It is impossible to set on the religious hypocrite and not lend him the language of piety. Consequently it appears that the mask of religious hypocrisy necessarily take on the occasion a character on religion itself. This was of the opposition to the play, and in a measure justified it bore out the consequence of 'Tartuffe' by an aggressive force. The translation of a part of this work is of Molière's: John Watts (London 1748).

Herbert F. V.

TASCHEREAU, tash'ur, Sir, Canadian jurist: b. 7 Oct. 1861-67 he sat in the Canadian Assembly representing Renne C. 1871 he was appointed judge of Superior Court, and (1878) judge supreme Court of Canada. He knight in 1902 and from 1902-06 justice of the Supreme Court of Can.

TASCHEREAU, Jules Antm, author and politician: b. Toux, Paris, 11 Nov. 1874. He studied at the Sorbonne, entered journalism, and in 1897 he entered the Chamber of Deputies. Meantime he had established himself as a journalist. Rene Pari was among the early supporters of l

5, The, a descriptive poem written
Cowper (q.v.) in the summer of 1783,
shed two years later in a volume con-
so "An Epistle to Joseph Hill, Esq.," 2
im, and "John Gilpin" (q.v.). It is

The Task, a poem with the same title
ving Milton a bit too plainly, and it
uted into six books, the aggregate
of lines being somewhat over
the metrical form, and the theme
he begins, "the sofa," are said to
ken by the poet from Lady Austen,
told him the story of "John Gilpin,
title commemorates the fact that in
we was obeying her injunction. The
the descriptions of which have per-
more than anything else to make the
classic standing not far below the
orate poems of the language, is that
in Buckinghamshire, and the neigh-
heeston. "The Task" set the seal on
popularity with his own generation
ceeding, and without it, despite

In his earlier pieces, notable in
range, he would perhaps not rank so
poet to-day, although it is to be
it too many readers know his mastery
through quotations, such as "God
made the country, and man made the town."
"With the spirit of life," the cups
of the spirit but not imbibe, and the
the, or else through selections such as the
pathetic description of "Crazy Kate," or the
national "England, with all thy faults I love thee still,
or the picture of the postman outside in the
winter evening, while all is domestic comfort
within, or the poignant bit of autobiography
that begins I was a stricken deer."

The
desultory and somewhat spun out "The Task" with
its longueurs, its exhibitions of intellectual
narrowness and religious bigotry, its comparative
lack of high and sustained imagination,
should tempt to skimming and even to tast-
ing by selections does not afford matter for
prise; yet the admirer of Cowper and the
student of English poetry must contend that
so to treat "The Task" is to stand in one's
own light. The ease and skill of the
transitions make the very desultoriness of the
poem an exhibition of art, Cowper an artist; but
west is still perhaps the most urban of our poets,
the descriptions of sceneries are scarcely
prized, as etchings in words, whether by
Thomson or by Wordsworth, and, although
there is little of the latter's philosophic insight
the heart of nature and into that of a man,
there is in compensation the absolutely sin-
cere expression of the observations, reflections
and emotions of a sensitive poetic genius un-
spoiled by literary or social sophistication.
When in addition we think of Cowper's play-
ful humor, his feeling for domesticity, his hu-
mankind, his satiric power — witness the
passage on the excise in the fourth book —
as exhibited in "The Task," we are led to
wonder whether our great-grandfathers
in their hearty appreciation of the poem as a
whole were not wiser than we are in our res-
ervations and in our glib phrases with regard to
Cowper's services as a precursor of the Geor-
gian romantics.

WILLIAM P. TRENT.

TASMAN, tás'mán, Abel Janssen (Jans-
zén, Janzoon), Dutch navigator: b. Hoorn,
North Holland, about 1602; d. Batavia, Java,
October 1639. He was engaged in the
 discovery in the Pacific and Indian oceans in
1638-42 under the patronage of Van Diemen,
 governor-general of the Dutch West Indies,
and in the latter year was sent to circumnavi-
gate Australia. He sailed from Batavia 14
Aug. 1642, discovered, on 24 November the
island which he called Van Diemen's Land, but
which has since been named Tasmania, and
later discovered the southern island of New
Zealand, the Friendly Islands, and the Fiji
Islands and returned to Batavia 5 June 1643.
Details concerning a subsequent voyage along
the coasts of New Guinea and north and west-
ern Australia are exceedingly scanty. He
set out on 29 Jan. 1644, discovered the Gulf
of Carpentaria, made other important dis-
coveries, and returned to Batavia, but further
information is lacking. He was one of the
great navigators of the 17th century.
He published a narrative of his first voyage
which was reprinted in 1722 and in 1860. Con-
sult his "Life" by Walker (Hobart, Tasmania
1896).
TASMAN (táz·man) SEA, Oceania, that part of the Pacific Ocean lying between Tasmania (and southeast Australia) and New Zealand. It is 1,500 miles across, and is crossed by a submarine cable from Sydney to Wellington.

TASMANIA, táz-ma´nit-a, Australia, the smallest state of the commonwealth, consisting of the island of Tasmania and its adjacent islets, and situated 140 miles south of the southeastern extremity of the Australian continent, from which it is separated by Bass Strait. The area of the state is 26,385 square miles, and of the main island 24,339 square miles. The main island is heart-shaped, about 180 miles long from north to south, and 175 miles at the widest. The coasts are bold and much indented, forming a number of excellent harbors. The interior is a plateau intersected in various directions by a number of rough and precipitous mountain ranges, rising in Cradle Mountain to a height of 5,069 feet. Some of the intervening basins contain large and beautiful lakes, and rivers are numerous. The geology is characterized by considerable outcrops of phaneritic rocks and extensive flows of tertiary basalt. The mineral wealth is great and mining is the principal industry. The annual value of mineral products is about $4,000,000, mostly gold and tin. The imports in 1916 totaled nearly $5,000,000 and the exports less than $4,000,000. The largest farm crop is oats, 2,000,000 busheled annually, wheat following with 1,000,000 bushels. The climate is temperate, and the rainfall in general sufficient. The flora and fauna are similar to those of southern Australia. There are two remarkable animals peculiar to the island, the Tasmanian wolf and the Tasmanian devil (Thylacinus and Dasyurus), sometimes called the native tiger. The soil is very fertile, especially in the basaltic regions, and well adapted for wheat, which is the principal crop. Grazing has declined, and the manufactures are inconsiderable. The volume of trade amounts to over $800,000 annually. The chief exports are copper, fruits, silver, wool, tin, gold, timber, hides and grain. Hobart, the chief port on the southeastern coast, has regular steamship connection with Europe, Australia, and New Zealand. There are about 600 miles of railroads. Education is compulsory. There are 16 colleges, and at the head of the educational system is the University of Tasmania. The capital of the state is Hobart with 38,000 population.

Tassero was discovered in 1642 by the Dutch navigator, Tasman, who named it Van Diemen's Land, after his patron. In 1804 England established a penal colony on the island. This was maintained until 1853, when Tasmania was declared a British colony. In 1900 it became a state of the commonwealth of Australia. The aboriginal inhabitants are almost extinct. There is a remarkable regular shifting of the population between Tasmania and Southern Australia, more than 40,000 emigrants and over 40,000 immigrants being officially recorded every year. Consult "Statistics of Tasmania" (Hobart, Australia). See Australia.

TASMANIAN WOLF, DEVIL, ZEBRA-WOLF, etc. See DASYURIDAE.

TASSAERT, tā-sār´t, Nicolas F. Octave, French painter; b. Paris, 1800; by suicide, 1874. He entered the studio of Girard and L�therie and made it his artistic aim to portray "Les Misérables" of Paris—the poor, the suffering, the wretched—his life. The exaggerated sentimentality of his pictures was much admired at the time. realism appealed even to Delacroix and Puvis. Among his best-known works are "Old Musician," "A Family of the Jews," "The Slave Merchant," and "Les Détroits." 

TASSIE, tāz´i, James, English engraver; b. Pollockshaws, near Glasgow, 1735; d. London, 1 June 1759. During his life he worked as a stonemason, then as a goldsmith, and later as an engraver. He was associated with Dr. Quin in gem engraving and his work, copied many of the most famous gems of ancient and modern times, and he made a series of large medallions for a number of the famous men of his time. Medallions are of great historic interest and considered his most valuable work.

TASSO, tās´so (Eng. tāz´o), B. Italian poet; b. Venice, 11 Nov., 1495; d. Padua, 5 Sept., 1569. His education was at Padua, where he studied medicine and music. He went to Rome where he studied law. His learning, took him into his service and employed him in negotiations with Clemente at Rome and Francis I in France. He gained the friendship of the Pope and the King of France. He was sent on public business to Spain and married the rich, beautiful and intelligent woman Porzio de Rossi, and retired to Sorrento, where he lived until 1547. He was made a knight of Malta and his life was spent in study. He was Charles V on account of his opposition to the Netherlands, the Introduction into the Inquisition into the Compelled poet, at the invitation of the Duke of Urbino, to take up his residence in Pessaro. The leisure which he now enjoyed, he employed in finishing his "Amadigi," which he published at Venice in 1560. In 1563 he was appointed the Duke of Mantua's ambassador to Spain. He was buried at Mantua, where he monument erected by the duke, with the inscription "Ossa Bernardi Tassae," by Torquato. Torquato afterward removed his body to Ferrara. His chief work is "Liber de Saula," a romantic epic, displays his power in art. His other works, in five volumes, are among the best Italian lyric and elegiac of the time. Consult Passoni, "I Greci di Torquato Tasso" (1885).

TASSO, Torquato, tōr´kwa´tso, preceding. Italian epic poet; b. Sorrento, 23 March 1544; d. Rome, 25 April 1595.

cardinal on an embassy from the
Charles IX of France. He was re-
d distinction at the court of France,
allowed to Blois, Tours and Chenon-
seard (q.v.) received him in the most
friendly spirit. A quarrel with his patron
drove him from the French court, and he
returned to Ferrara, where Alfonso, at the solicita-
tion of his father, conceived a
into his own service. In the spring of 1573 his
'Aminta,' a pastoral drama, was represented at
the court of Ferrara. It is still considered
the most graceful Italian work of the kind, al-
though many prefer the 'Pastor Fido' of
Guarini. In April 1575 he announced the com-
pletion of the 'Gerusalemme.' Alfonso
was eager for its immediate publication, but this
judicious counsel was not heeded by the poet,
whose sensitive mind dreaded censure, especially
the censure of the Church, even more than it
 coveted applause. He, therefore, sent his poem
to his friend Scipio Gonzaga, now a cardinal
at Rome, requesting his judgment. Scipio as-
sembled a consulta of churchmen and critics
against whose censures, literary and ecclesia-
tical, the poet was forced to defend himself and
to amend and modify his work to meet their
views. He was told he ought to be content
with monks and nuns as his auditors, and to
renounce all mythology, romance and chival-
rous adventure, and his mind, divided between
art and religion, gave way. To add to his dis-
traction his work at this time was printed pi-
 ratically without his own revisions. Alfonso
wrote a vigorous protest against this disgrace-
ful proceeding to all the Italian courts, but
his doubts of his favor at court began also to fill
the mind of Tasso. He believed that he was
persistently calumniated at court, and systema-
tically misrepresented to the Inquisition. On
17 June 1577, he drew his pen in the apart-
ment of the Duchess of Urbino. He was ar-
rested, but set at liberty after two days and
recommelled to retire to his country-seat. In
spite of strong reassurances he still suspected
the office at Rome. He was now received into
the convent of Saint Francis at Ferrara, but
on the 20th July he started in disguise for his
native place where he stayed with his sister
Cornelia, till the end of summer. In the
autumn he solicited leave to return to Ferrara,
and obsequiously accepted a condition that
was essential to his request. Alfonso is accused of
imprisoning him, first, from offense at the add-
dresses paid to his sister; secondly, from jeal-
osy of the Medici, from whom the poet had
received an offer; and thirdly, from a fear that
the poet would strike the glory of the house of
Este out of his work. For some years Tasso
had lived on intimate terms with Alfonso and
his two sisters, especially Lucrezia, who, dis-
missed by her husband, kept him as her con-
temporary companion. He had hesitated about ac-
cepting the offer of the Medici, but in 1557 he
put away, out of gratitude to the Este family,
all thoughts of other service. After many
complaints of ill-treatment he again left Fer-
rara, and wandered, sometimes in want,
through Padua, Venice, Urbino and Piedmont,
and finally returned to Ferrara (21 Feb. 1579),
on the eve of the duke's second marriage.
Finding himself treated with complete neglect,
he broke out in loud complaints and was ar-
rested as a madman in the hospital of Saint
Anne of Ferrara. At this time his work was
condemned by the Academy della Crusca, to
whom he replied with moderation. He re-
mained in the hospital of Saint Anne till July
1586, when he was released at the solicitation
...
of Vincent di Gonzaga, who took him to his estates. Tasso now resided at Mantua, and was requested by order of the court to write a genealogical poem he dedicated to Vincent di Gonzaga. Finding that Mantua did not agree with him, he proceeded to Naples, the climate of which he found most congenial, and where he fixed his favorite residence at the monastery of San Salvatore. Here he composed the "Gerusalemme Conquistata," which he dedicated to Cardinal Aldobrandini. It is a reconstruction of the "Gerusalemme Liberata," in which he rejects the chief mystical and chivalrous ornaments of the previous poem, and plumes himself on a precise and slavish imitation of the "Liad." He wished it to supersede the "Liberata," but posterity has reversed his decision as to its superiority. Aldobrandini solicited and obtained from the pope an indulgence on behalf of Tasso. Urged by his patron, Tasso repaired to Rome, although he declared it was to die. Amid the preparations for the ceremony, his health gave way. He retired from the plaudits of the public to the consent of Santo Spirito (Aminta; Jerusalem Delivered). Tasso's chief works include "Gerusalemme Liberata," the "Rime," and the "Aminta." The "Gerusalemme" was translated into English by Edward Fairfax in 1600. In Italian literature the "Gerusalemme shares with the "Orlando" of Ariosto the place of the greatest epic. Both are full of poetic beauties and admirable for the interest and variety of the narrative. Consult Albertazzi, A., "Torquato Tasso" (Modena 1911); Boulingu, W., "Tasso and his Times" (New York 1907); Milman, R., "Life of Tasso" (2 vols., London 1880); Ferruzzi, E., "Tasso, studi biografici e critici" (1880); Serassi, A., "La vita di T. Tasso" (3 ed., with notes by Guasti 1858); "Complete Works" (3 vols., Pisa 1821-32); Tasso's "Lettere e Dialoghi," edited by Guasti (Florence 1852-59); "Prose diverse" (1825); Solerti, A., "Vita di Torquato Tasso" (3 vols., Turin 1885); de Sanctis, F., "Storia della letteratura italiana" (2 vols., Paris 1912); Sainati, A., "La briga di Torquato Tasso" (Oplonti 1912); Scopoli, "Le fonti del mondo creato di Torquato Tasso" (Naples 1907); Wagner, Hedwig, "Tasso daheim und in Deutschland" (Berlin 1905); Woodberry, G. F., "The Inspiration of Poetry" (New York 1910).

TASTE, in aesthetics, appreciation of the beautiful; the faculty of discriminating the qualities of beauty, harmony, etc., and exercising them, particularly in art, and literature, jointed to a capacity for appreciating and enjoying excellence. See AESTHETICS.

TASTE. See SENSES.

TATARS, or TARTARS, a nomadic people generally spoken of as Scythians, known for their invasions and conquests among neighboring nations over a wide extent of territory; their local seat being found both in ancient and modern times in the steppes or uncultivated regions which were afterwards as well as at the north of China, in Turkestan and on the shores of the Caspian and Black seas. Tartar, Tatar or Tart appears to have been the name of a tribe of Mongols who occupied about the same district of China Tartary on the upper Amur. This tribe was dispersed by the attacks of neighboring Mongols, among the terror of its arms in different parts of Asia and Europe, and gave rise to various hordes of Mongol robbers. The Tatars formed part of the hordes of the Ogorkh Khan, when that conqueror carried with him the country known as Chinese Turchia, and according to some accounts the name to be applied to the Mongol horde, as well as to the hordes of similar origin who followed the footsteps of the Tartars, and settled in the districts from which they came, or in which they settled; hence the name "Tatar," transitory, for a Mongol robber. See Amur, Turkestan, and Little Orenburg, Astrakhan, Ekatereinoslav, the sack provinces and the Crimea.

TATE, tâ, Alexander Norman, analytical chemist: b. Wells, Somerset, 1837; d. Orton, Cheshire, 22 July 18. He studied chemistry in Liverpool, where he published an analytical and consulting laboratory in 1863, and the results of industrial science in connection with the study of the recently introduced petroleum. He wrote "Petroleum and its Uses" (1863), and superintended the planning and management of oil-refining works in the Isle of Man and in Flintshire until he finally settled at Hackins Hey and became an expert in the analysis of fats, and as a teacher of science technical schools at Liverpool. He was editor of the scientific magazine Regress (1864-70) and a contributor to scientific periodicals.

TATE, George, English archaeologist: b. Alnwick, 1805; d. there, 1871. He was a linen draper and sub-postmaster of his native town and became, for his scientific researches and publications. These include: "The History of the Antiquity of Graveshall"; "The Hut-circles at Yevington Bell;" among the long list of his papers on the ancient remains of the city, its geology, flora and fauna, and tured Rocks of Northumberland and Borders," (1865) and "History of . . ." (1865-69).

TATE, Henry, English merchant: b. Chorley, Lancashire, Streatham, 5 Dec. 1889. He was a merchant in Liverpool and amassed a fortune through the invention of leaf sugar. He moved to London in 1880 and became known as a benefactor, giving £42,000 to the University College, a still larger sum to the hospitals and four free beds to the parish of Lambeth. He established a private gallery of modern paintings and art, and afterwards presented it to the building for the collection a gallery of pictures at Tate Gallery, where it was opened in 1897, and its donor was created a baronet, known as the "Tate Gallery."
TATE — TATTOOING

The Tatler was succeeded by The Spectator (q.v.).

TATTERSALL’S, tät’är-sällz, located in Knightsbridge Green, London, England, is the great metropolitan mart for horses, of which there is an auction every Monday throughout the year and every Thursday in spring. It has acquired greater celebrity as the head-quarters of betting men.

TATTI, tät’te, Jacopo. See Sansovino, Jacopo.

TATTNALL, tät’nål, Josiah, American naval officer: b. Bonaventure, near Savannah, Ga., 9 Nov. 1795; d. Savannah, Ga., 14 June 1871. He was educated in England and in 1811 returned to the United States. He was appointed midshipman in the navy. He was engaged in the battle of Bladensburg and served in the Algerine war in Decatur’s squadron. He was promoted lieutenant in 1818 and was engaged in the suppression of the West Indian piracy under Porter in 1823-24. He was promoted commander in 1838, placed in charge of the Boston navy yard and at the outbreak of the Mexican War was assigned to the command of the Spitfire and joined the squadron at Vera Cruz. He took charge of the Mosquito division, with which he covered the landing of General Scott’s troops, and after the fall of Vera Cruz led the attack on the forts at Tuspan. He became captain in 1850 and in 1857 was appointed flag-officer of the Asiatic squadron, where he participated in an attack with the French and British on the Chinese. Although a violation of neutrality, he was sustained by public opinion and also by the government. In 1861 he resigned from the United States navy and offered his services to the governor of Georgia. He was appointed captain in the Confederate navy, took command of the Merrimac after the engagement with the Monitor in 1862 and set out for Hampton Roads. After the surrender of Norfolk and the navy yard he withdrew with the Merrimac, and on 11 May 1862 to prevent her capture sunk her off Craney Island. The court-martial, which he requested, after a thorough investigation acquitted him from all blame. He then engaged in the defense of Savannah River, but in 1865 was compelled to destroy his vessels. In 1870 he returned home and was appointed inspector of the port of Savannah, a post which he occupied until his death. Consult Jones, C. C., ‘Life of Commodore Tattnall’ (1878).

TATTOOING, a word of Polynesian origin, anglicized from the Tahitian iatu, denoting the practice of making permanent designs or figures in the skin by means of small punctures or incisions, which receive various dyes or pigments. The coloring is mainly dark blue and dull red. A similar custom, known as cicatrization or scar-tattooing, consists in repeatedly cutting the skin at the same place so that in healing a raised scar is left. Both varieties of tattooing may be found among the same people, as in the case of the natives of the South Sea Islands. Among the Admiralty Islanders, the Fijians, the Gonds and the Todas of India, the inhabitants of the Liu-Kiu Islands and other races, color-tattooing is, or was, confined to the women, and the Latuka

*
of the upper Nile Valley are an example of a people among whom scar-tattooing is practiced. Color-tattooing is generally ornamental, but scar-tattooing is more frequently used to produce distinguishing tribal marks. The latter variety is practised by a number of native African peoples, while the Bangala of the Middle Congo scar the whole body for ornamental purposes. In some races there is a connection between tattooing and marriage. Thus, in the Solomon Islands a girl is not eligible for marriage until she has been subjected to an atrociously cruel process of tattooing on the face and chest, and the native Australians inflict fearful scars on the backs of their young girls before marriage. The Formosans tattoo the faces of girls prior to marriage; and among the Papuans of New Guinea unmarried girls are tattooed all over except on the face, which is adorned in this way at the time of their marriage. Color-tattooing of an ornamental kind reached its most artistic development among the Maoris of New Zealand and the Japanese, but both these peoples, like several others, have largely abandoned the practice under the influence of civilization. With the Malays tattooing appears to have been a reward of the successful head-hunter. Sailors and some other classes in civilized countries do this in order to distinguish themselves, and even in one color, making figures, as stars, flags, etc., on their heads, arms, chests, etc. Consult Robley, H. G., 'Moko, or Maori Tattooing' (London 1896).

TAUCHNITZ, town'shis, Christian Bernard, Freiherr von, German publisher; b. Schleinitz, near Naumburg, 25 Aug. 1816; d. 13 Aug. 1895. In 1837 he founded his well-known publishing establishment in Leipzig; in 1880 was created a hereditary noble; in 1886 was appointed consul-general for Great Britain in the kingdom of Saxony; and in 1877 was made a life member of the Saxony first chamber. The firm is best known for its collection of British and American Authors, generally called the "Tauchnitz Edition," begun in 1841 and in 1903 extending to about 3,700 volumes.

TAUCHNITZ, Karl Christoph Traugott, German publisher; b. Luckenwalde, Silesia, near Grimma, 29 Oct. 1761; d. 14 Jan. 1834. In 1797 he set up a printing shop at Leipzig, which he enlarged by the addition of a book-shop in 1798 and a type-foundry in 1800, the style of the firm being Karl Tauchnitz. He first introduced stereotyping into Germany, and won a high reputation by his musical publications, his editions of the Bible and the Koran and his remarkably correct series of Greek and Latin classics.

TAULER, tow'lur, Johann, German mystic; b. Strasbourg, about 1300; d. there, 16 June 1361. At 18 he denounced a fortune to enter the Dominican cloister, where he studied the scholastic theology, and returning to Strasbourg came under the influence of Master Eckhart, whose vernacular sermons then attracted throug his audiences. He was the more impelled to mystical and fervent piety by the violence of the war between Pope John XXII and the Emperor Louis the Bavarian, when the bishop of Strasburg forbad the clergy to open the church doors in the name of the so-called "friends of God," an unorganized brotherhood, including priests, nobles and burghers in all the large cities, who represented the heresy, denied the special prerogative of Christ, and contradicted the Scriptural precepts and with an acerbous spirit tended upon the worship in the heart and life. He preached with wonderful success in Str and in the neighboring towns, villages and cottages. Withstanding the papal interdict and the ravages of the black death (1348), he bestowed the consolations of religious consolation upon forsaken people, preaching in German rather than with Latin. He published in German a Life of Christ. Following the Lowly Life of Christ, he published a Remonstrance to the Clergy, leaving the dying unattended and unburied, and denounced ecclesiastical abuses while removing the claims of the electors. His onism, though it pronounced silence and led the most perfect work, was rather than passive, taught explicitly the love of to asceticism but to the amelioration of society. The discharge of the religious duties as a preparation for the development of spiritual perfection as an important duty, was the German theology which had been advocated by the pantheistic movements of F. C. Schmidt, 'Johannes Tauler von Straßburg' (1841); Winkworth, 'Life and Times of Tauler,' with 25 of his sermons translated from German' (1857); Junot, 'Les Amis de Dieu du XIVe Siècle' (1870).

TAUNTON, town, England, a port of Somerset, on the Tone, 36 miles south-southwest of Bristol. The principal buildings and institutions are the churches of Saint James and Saint Mary, and in the old grammar school, reconstituted as a Wesleyan Methodist and a Congregational College, a mechanics' institute, and a museum. The great antiquity, and from the discovery of containing Roman coins appears to have a Roman station. During the Civil War the city was of the Parliamentarians against the Royalists. The inhabitants suffered much from the rebellion of Monmouth, whose cause espoused, and who assumed the title of Prince here on 20 June 1685. Jeffrey (q.v.) was here in the same year.

TAUNTON, Mass., city, county, and county seat of Somerset County, at the head of navigation on the Taunton River, and about 36 miles southeast of New York, New Haven and Hartford road, about 36 miles southeast of New York, and 16 miles north of Fall River. There are some 2 steamers, which have daily connection New York and other places, are so near to that they practically. Taunton has a daily newspaper and about 100 freight cars enter the city daily. The Taunton River is with the Atlantic ports. The city gets its coal, lumber at tide water, and freight rates.
Taunton are less than for inland cities. Inns connect the nearby villages and the city, more than 700 cars leave of the city daily. Industry is noted for the extent and diversity of manufacturing industries. The government of 1910 gives the leading establishments of the city as follows: one bank, 161; insurance, 2; and 3,151 persons, to whom were paid $1,125,679. The cost of the material ally was $2,651,502, and the value of products was $4,592,466. There were 367 im and machine shops, with capital $2,679,203; the value of their yearly $2,636,360. The total number of manu- (1909) was 146; the total capital in 5,504,000; the average annual revenue, 7,855; the annual amount of $55,000; the cost of material used; and the value of the products, 1. The principal manufactures, bend products, are cutlery, machinists’ lads, tacks, nails, jewelry, machinery as manufacturers, silver and Britannia k, oil-cloth, copper and yellow metaling presses, stoves, stove linings and ensils. The city is the distributing a large part of Bristol and adjoining, coal is shipped from here to the i, the interior, and grain, vegetables, id manufacturers to outside markets. incipit public buildings are the State hispal, a massive group of buildings, a tract of 140 acres, which accommodates 1,000 patients; the county courthouse r: $300,000; Registry building (cost the government building ($100,000); Taunton jail; theatre; Odd Fellows’ storical Hall; Morton Hospital, the san Tillingham Morton Kimberly; Old sime, opened January 1871; club build- s, business blocks and. There are six each of Congregational Catholic churches, four Methodist, of Unitarian, Baptist, Presbyterian, Scientist, Adventist, Protestant Episcopal Universalist. The educational insti- Academy, opened 1 August Mary Academy (Roman Catholic); of the Old Colony Historical So- porated 4 May 1853; a high school, l parish schools, graded elementary sa public library containing about 70,000. The city is well supplied with the two national banks had, 0, a combined capital of $700,000; the surplus of two savings banks was and five co-operative banks had a capital of over $3,000,000. The gov- f the city is vested in a mayor and aldermen chosen by popular vote. Pop. 51.

— The first white settlement was by Elizabeth Pole, an Englishwoman, in 1630. There was an Indian village called “great river” on the Tectucutt River. Bought land from the Indians for on the east side of the river, present limits of Ward Four. The first called Cohasset, but when it was settled in 1639 it was called by its name, after Taunton, England. In June 1639 Taunton sent deputies to the General Court assembled at Plymouth. The name which appears on the Taunton records — early connected with the surveys and the granting of titles — are names of men who were among the history makers of the nation. The early settlers of Taunton recognized the rights of the Indians, and the records show that Miss Pole and others purchased lands from Massasoit and other Indians. William Hooke, the first minister, returned to England as domestic chaplain to Oliver Cromwell. The first mention of a schoolmaster is that of Master Bishop, who was one of the early settlers. Other schoolmasters were William Pole, Mr. Adams, James Green, and in 1683, Samuel Danforth, a minister, was selected to keep a “Grammar school here in Taunton.” In 1647 an act was passed which made the public schools free and the support of the schools compulsory. In 1682 Taunton received from the court £3 from the funds of the fishing excise of the Cape, for keeping a free colonial, classical and elementary school. In 1701-02 100 acres of land, on both sides of the river, were set apart for school purposes. The history of education in Taunton is an almost complete history of the city. A grist mill was erected in 1639-40; in 1653 the first successful iron works in America were established. Some of the products of the iron works were used as money, as may be seen from the following order:

To the Clerk of the Iron Works,

Ensign Thomas Leonard, please pay to Bar Tipping nine shillings and three pence in iron money.

From yr. friend,

Richard Williams,

Taunton 16th Jan. — 1685.

In 1659-60 a saw-mill was built, and before 1700 brick making, shipbuilding, and many other industries had been begun. The ruins and sites of many of the old manufactories are pointed out as of historic interest; for they mark the beginnings of the mighty industries of the Taunton of the present. On 6 Nov. 1746 the place was made a “shire town,” and on 2 Jan. 1863 was incorporated as a city. The first crucibles in America were made here; the copper blank discs for copper cents were supplied to the government, in large amounts, by the Taunton Manufacturing Company. Taunton has always furnished promptly more than its quota of soldiers when the country called for defenders. In 1774 the people unfurled from the liberty pole on “Taunton Green” a flag, on which was inscribed “Liberty and Union”; and among the “minnitt men” at Lexington, 19 April 1775, was a brave band from Taunton. They were among the first to go and the last to return. Robert Treat Paine, one of the signers of the Declaration of Independence, resided here, for whom a statue has been erected in front of the city hall. Consult Waterman, “History of Taunton School.”

TAUNUS, town of, Germany, a mountain range mainly in the Prussian province of Hesse-Nassau, extending eastward from the Rhine, north of the Main, separating the basin of that river from that of the Lahn. The highest summit, Grosser Feldberg, 2,280 feet in elevation. The district is well wooded, and ex-
TAURID A—TAVERNIER

hibits much picturesque scenery, as well as ruined castles, etc., and antiquities remain dating from Roman times. Its scenery and mineral waters attract many visitors; and some of the finest German wines are grown on the south side. The point of most historical interest in the region is the ancient Roman fort uncoverd at Saalburg, showing fortifications dating back to the year 200. West of Saalburg the Germans erected a colossal statue of Germania to celebrate their victory over France in 1870-71.

TAURIDA, tow're-da, a government of the Ukrainian Republic, bounded north by Ekaterinoslav; east by the Sea of Azov; south-east, south and west by the Black Sea; and north-west by the government of Kherson, from which it is separated by the Dnieper; area, 23,312 square miles. It is irregular in shape, and being united to the land only on its boundary with Ekaterinoslav for about 90 miles, may be regarded as one large peninsula, subdivided again into two minor peninsulas, of which that in the south, now called the Crimea, and well known in ancient times as the Chersonesus, is the more perfect; the island which constitutes it in the northern portion being at its narrowest not more than eight miles. The northern peninsula consists almost entirely of an extensive steppe, which stretches across into the southern peninsula, largely, as it is much cut up by innumerable lakes, and in many parts composed of parceled and saline sands, where vegetation is almost extinct; but in other parts is composed of fertile loams, capable of raising any kind of crop, and often covered with waving pastures. Simferopol is the capital city. (See also the article CRIMEA.) Pop. about 2,133,000.

TAURUS, târ'ús, Asiatic Turkey (or Asia Minor), a mountain chain or series of mountain groups usually considered as beginning in the east on the Euphrates, at the Nushar Carataet, in the pashalic of Marash, whence it stretches west, nearly parallel to the coast of the Mediterranean, for above 500 miles, terminating to the north of the Gulf of Adalia. In the east it takes the name of Jebel Kurun, or sometimes Anti-Taurus Mountains, in the west that of Dagh-e Balabar. It sends off several branches, of which the most remarkable are Alma-Dagh, which proceed south into Syria, and becomes linked with the chain of Lebanon; and the Anti-Taurus, which proceeds north-east, sending out ramifications which become linked with Ararat, Elburz and Caucasus. Many of the Eastern peaks are above 10,000 feet.

TAURUS, the Bull, in astronomy, a name given the second of the zodiacal constellations. It contains the star of the first magnitude Aldebaran (in the eye), the group of the Pleiades (in the neck), and the Hyades (in the face).

TAUSEN, Hans, Danish reformat; b. Birkenel, on Fanen Island, 1494; d. Ribe, 11 Nov. 1561. He studied at Wittenberg and was preacher, from 1525, at Viborg, then, from 1529, at Copenhagen. He edited, with collaborators, in 1533, The 4th Copenhagen Artiz. The 13th edition of 1535 has published a work called a book of homilies. He was appointed reformed master of the university (1537) and (1542) bishop of Ribe. Instead of Latin he used his native language in his sermons and books. A selection of his works was brought out by Rödamin (Copenhagen 1870). Consult Rödamin, 'Skiaographia Lutheri Danici M. Johannes' (1757); Schmitt, L. 'Johannis Tausen, oder der dänische Luther' (Köln 1894).

TAUSIG, Karl, German pianist: b. Warsaw, 4 Nov. 1841; d. Leipzig, 17 July 1871. First he was under his father’s tuition, then studied under Schubert, in Vienna. He made art tours, then lived in Dresden and later (1861-62) in Vienna. From 1866 he was royal court pianist at Berlin and led, till 1870, an academy of pianoforte playing. As a virtuoso he was equally interpreter of classic as of modern piéce-music, but as composer he produced few works. Noteworthy of his productions is his edition of Clements’s 'Gradus ad Parnassum.' His piano score of Wagner’s 'Meistersinger' became very popular. His 'Technischen Studien' was published by H. Ehrlich. Consult Weitzmann, 'Der letzte der Virtuosen' (Berlin 1866).

TAUSSIG, tow'sieg, Edward David, American naval officer: b. Saint Louis, Mo., 20 Nov. 1847. On graduating from the United States Naval Academy in 1870, he was appointed ensign, master and lieutenant, being made lieutenant-commander 19 June 1892. He has served on the European, and Pacific stations and in the coast survey. He took possession of Wake Island for the United States and was placed in charge of Guam 1 Feb. 1899. He was on duty in the Philippines and during the summer of 1900 in North China. He has commanded the Bennington and the Yorktown.

TAUSSIG, Frank William, American political economist: b. Saint Louis, Mo., 26 Dec. 1859. He was graduated at Yale 1887, and has been full professor of political economy there since 1892. He has written 'Tariff History of the United States' (1st ed. 1888; 6th ed. 1914); 'Silver Situation in the United States' (1892) ('Wages and Capital' (1900); 'Principles of Economics' (1911); 'Some Aspects of the Tariff Question' (1915); 'Inventors and Moneymakers' (1915), and has been editor-in-chief of The Quarterly Journal of Economics.

TAUTOG, a marine fish (Tautoga omilus) of the Atlantic Coast of the United States, related to the cunners and wrasses of the family Labridae, and locally known as blackfish or oysterfish. It is from two to three feet in length, when large, blackish in color, the young with about three pairs of obscure dark bars; chin white; eye greenish. It abounds about weedy rocks, oyster reefs, etc., near shore, feeding on mollusks, barnacles, etc., and is easily caught. It is one of the best table-fishes of the American coast. The annual catch off the New England coast is about 750 tons.

TAVERN, a name common especially in the rural districts of Great Britain and the United States for a village inn or hotel. Occasionally some city hotel has borne the name.

TAVERNIER, JEAN-BAPTISTE, French valet de chambre: b. Paris, about 1605; d. Copenhagen, 1689. Before his 21st year he had visited a considerable portion of Europe. He subsequently traveled through Turkey, Persia and other Eastern countries, six times by different routes, trading as a dis-
rechant, and studying manners and cus-
f his journeys he gave an account, assis-
ting him in his literary work. In-
ing realized a large fortune and ob-
potent of nobility, he retired to the

I TAWI, tā-wē tā-wē’, Philippines,
oup of islands of the Sulu Archipelago,
the extreme southwestern part of the
es, consisting of 88 islands; area, 462
miles. Some of the islands, though
are unnamed; the others are divided
sub-groups or clusters; (a) the Cina-
Kinapusan cluster; (b) the Tawi Tawi
and (c) the Laparan cluster. The area
is mountainous, but of moderate
he valleys and plains are fertile and
with tropical vegetation. Rice, corn,
d coffee are cultivated, but only for
use; the forest wealth is considerable,
ct of commercial value on account of
transportation. The chief in-
ishing, pearl fishing and gathering
of-pearl, etc. The islands are sparsely
populated and, as many are very inaccessible,
have been for many years the hiding places of
pirates; the few settlements were originally estab-
lished by the Spaniards. (2) The largest and
name island of the Tawi Tawi group; length
from northeast to southwest, 35 miles; greatest
width, 15 miles; area, 187 square miles. It is
mountainous, and of volcanic formation; there
are three groups of two peaks each, one at the
southern end, one at the northern end and the
third in the east central part; greatest elevation,
1,941 feet. The soil is generally fertile, and the
island well wooded; the chief industry, as in
the rest of the group, is fishing. Taws chief
settlement is Tatun, on the northwest coast,
on a small bay.

TAWNÉY, James A., congressman:
near Gettysburg, Pa., 3 Jan. 1855; d. Excelsior
Springs, Mo., 12 June 1919. He was educated
at the common schools and learned the black-
msmith’s and machinist’s trade. He went to
Winona, Minn., in 1877 and worked there as a
machinist for four years. He was admitted to
the bar there in 1862 and practised law until
1889, when he was elected to the State senate
of Minnesota. In 1893 he was elected to the
53d Congress and served continuously until
1911, when he was defeated by the Progressive
party. Mr. Tawney was appointed by ex-
President Taft to the International Joint Com-
mission created by treaty with Great Britain
for the settlement of disputes between the
United States and Canada, and was chairman of
the United States section of the commission un-
til his death. Mr. Tawney had great political
power in Minnesota, and took an active part
in the anti-trust legislation, in 1907 he was
vice-chairman of the Republican Congressional
Campaign Committee. He was known in the
Republican party as an insurgent and continually
surprised the Republican machine while in Con-
gress by bolting. He was an orator of great
power. He was chairman of the House Ap-
propriations Committee until 1910, and long
championed a Federal budget system. Tawney
was defeated for re-election in 1910, when he
opposed reform of the power of the speaker
of the House. In 1910 he opposed the efforts
of the Republicans to increase appropriations
for the army and navy.

TAX ASSESSORS. See TAXATION.

TAX-DEED, an instrument or conveyance
whereby the proper officer of the law undertakes
to convey the title of the rightful owner to the
purchaser at a tax sale or a sale of the land for
non-payment of taxes. This deed, according to
the principles of the common law, is simply
a link in the chain of the purchaser’s title. It
does not of itself transfer the title of the owner,
as in grants from the government of deeds
or as do conveyances between individuals. The
deed is not the title itself, or even evidence of
it, its recitals not being binding. No presum-
tion arises upon the mere production of the
deed that the facts upon which it is based
really existed, but when it is shown that the
officers of the law have performed every duty
imposed upon them the deed becomes conclusive
evidence of the title in the purchaser.

TAXALES. See PALEBOTANY.

TAXATION. What Is a Tax? — A
distinction must be made between a tax and the
exercise of the power of taxation. Property may be taken from individuals by the government under the title of various sovereignty as powers, such as the power of eminent domain, the penal power, the police power and the taxing power. Where the purpose of the compulsory payment is neither to exercise the right of eminent domain nor for punishment nor primarily for purposes of regulation, we have to deal with the power of taxation. The power of taxation may be exercised, however, in several ways. The government may perform a service for the individual from which a specific benefit is received and where the cost of the service is presumed to be covered by the payment. Such payments are called fees or tolls. Or, again, the government may, with or without the consent of the individual, make an improvement which increases the value of his real estate and may impose what is technically called a special assessment or a betterment charge. Finally, the government may impose a payment on the individual where the special benefit, if any, is merely incidental. Such a payment is called a tax. The narrower sense are to be distinguished, therefore, not only from fines and penalties as well as from prices (charges made by the government when it carries on a commercial or industrial undertaking) but from fees or tolls and from special assessments, both of which are equally manifestations of the taxing power, but which are distinguished from taxes in the narrower sense in that the special benefit accruing to the individual is both positive and measurable.

A tax may, therefore, be defined as a compulsory contribution from the person to the government to defray the expenses incurred in the common interest of all, without reference to special benefits conferred. Each word in this definition is significant. A tax is a contribution, whether in money or in kind; it is compulsory (to distinguish it from a gift); it is paid by a person—either a natural person, like an individual, or an artificial person, like a corporation; it is paid to the government in any of its forms, whether local, State, Federal or international; the expense must be incurred in the common interest of all, or, in legal parlance, it must be for a public purpose; otherwise it is confiscation, not taxation. Finally, it must be paid without reference to special benefits conferred. It is levied for the common benefit, not for any special benefit.

The Reason of Taxation.—By the reason of taxation is meant the ground or the philosophical justification of taxation. The older theory may be called the exchange or the contract or the reciprocity theory. It was connected with the 18th-century contract theory of the state. This theory holds that taxes are a mere exchange between the individual and the government. The point is that the individual gives the government something in return. This theory has been completely superseded by the more modern political philosophy. The modern theory may be called the cost or the race or the theory of taxation. It does indeed deny the obligation of the government to do something for the community in return for the payment exacted from the community. In this sense, indeed, reciprocity; but it is an exchange the community cost only for the government something which represents the community cost only for the state. He is born into the state, transfers his political allegiance, without any reservations. In this sense the state is as much a part of the individual as the individual involuntary assumes obligations to his family, so he assumes obligations to the state in which he is. It is, therefore, as much his duty to support the state as it is to himself. The obligation to pay tax, therefore, be declared in modern in a natural obligation and the state is justified in converting this moral obligation to a legal obligation.

The Function of Taxation.—The function of taxation, therefore, is to revenue. This may be declared to be the function of taxation. As a matter of fact, taxation has always been for other purposes which may be declared secondary or incidental in character. A function may be declared the social, rather the fiscal, function of taxation. Taxation has at various times employed an imperative power to destroy or to foster economic activity. At the present time, in the States, for instance, we have a tax which utterly destroys the pro phosphorus matches. We have, or taxes designed to foster or prohibit forms of domestic industry. In that there have been two extreme schools of the one represented in the United Statesmen like Calhoun or publicists like A. Wells, who have contended that the primary function of taxation is fiscal and, for instance, means con other extreme represented by such and by professorial socialists like A. T., have maintained that the primary function of taxation is to effect changes. A logical corollary of this position that no payment can be required that it seeks to effect social changes. In modern and more moderate positions, while the primary function of tax be the fiscal function, there is a refusal to bring about, incidentally, taxation, desirable social reforms that are as such the community. The Nature of Taxation.—Is it good or a bad thing? Is it a
TAXATION

Here again we have two schools of thought. The older writers, of whom Jean Say is a good example, adopted the consumption theory of public finance, that governmental functions ought to be supported by a minimum and that the exercise of governmental functions is burdensome upon the community. The tax is that the government spends for the public welfare is based upon the productivity of the community. The nice is that all government expenditure should be reduced to a minimum and that, as far as is possible, the producers should be the only or the chief productive people. Some taxation may be legal, political or economic. The legal limitations upon taxation are creatures of positive law. The government, in the United States for instance, is enjoined from levying a tax on exports. The State governments are prohibited from levying any taxes which will interfere with interstate commerce. Both State and local governments are frequently enjoined from levying more than a maximum rate of taxation. The political limits of taxation may be illustrated by the provision of American law, that all taxes must be for a public purpose. The exact formula of what constitutes public purpose is something which has given great trouble to our judges and legislators. The limits of taxation are seen when we reflect that the ultimate source of all taxes is the social income and that the demands of government in the form of taxation may trench unduly upon this income. We have seen how many forms of taxation have been used with the expectation of being of a tax. If the expenditure is a waste, it is a proper use of the American colonists, there were three fundamentally different systems of taxation, corresponding to the system of small farms and petty industry in the New England colonies, to the dominance of business interests in the middle colonies and to the plantation system in the Southern colonies. The fiscal system of the feudal ages rested largely upon land. The success of the tax on personal property was and is very different in the towns from what it was in the country. The growth of modern forms of business has brought with it an entirely new system of taxation. The main influence is attributable to the introduction of the modern system of progressive taxation. In the third place, we note the development of the idea of limits to be expected, but in relation to the source from which taxes are derived. It is a question not what do you do with the tax, but from what source do you get the tax? In other words, no matter how ideal in other respects a tax is, it may impose too heavy a burden upon the community. The limits of taxation may be legal, political or economic. The legal limitations upon taxation are creatures of positive law. The government, in the United States for instance, is enjoined from levying a tax on exports. The State governments are prohibited from levying any taxes which will interfere with interstate commerce. Both State and local governments are frequently enjoined from levying more than a maximum rate of taxation. The political limits of taxation may be illustrated by the provision of American law, that all taxes must be for a public purpose. The exact formula of what constitutes public purpose is something which has given great trouble to our judges and legislators. The limits of taxation are seen when we reflect that the ultimate source of all taxes is the social income and that the demands of government in the form of taxation may trench unduly upon this income. We have seen how many forms of taxation have been used with the expectation of being of a tax. If the expenditure is a waste, it is a proper use of the American colonists, there were three fundamentally different systems of taxation, corresponding to the system of small farms and petty industry in the New England colonies, to the dominance of business interests in the middle colonies and to the plantation system in the Southern colonies. In the third place, we note the development of the idea of limits to be expected, but in relation to the source from which taxes are derived. It is a question not what do you do with the tax, but from what source do you get the tax? In other words, no matter how ideal in other respects a tax is, it may impose too heavy a burden upon the community. The limits of taxation may be legal, political or economic. The legal limitations upon taxation are creatures of positive law. The government, in the United States for instance, is enjoined from levying a tax on exports. The State governments are prohibited from levying any taxes which will interfere with interstate commerce. Both State and local governments are frequently enjoined from levying more than a maximum rate of taxation. The political limits of taxation may be illustrated by the provision of American law, that all taxes must be for a public purpose. The exact formula of what constitutes public purpose is something which has given great trouble to our judges and legislators. The limits of taxation are seen when we reflect that the ultimate source of all taxes is the social income and that the demands of government in the form of taxation may trench unduly upon this income. We have seen how many forms of taxation have been used with the expectation of being of a tax. If the expenditure is a waste, it is a proper use of the American colonists, there were three fundamentally different systems of taxation, corresponding to the system of small farms and petty industry in the New England colonies, to the dominance of business interests in the middle colonies and to the plantation system in the Southern colonies. The fiscal system of the feudal ages rested largely upon land. The success of the tax on personal property was and is very different in the towns from what it was in the country. The growth of modern forms of business has brought with it an entirely new system of taxation. The main influence is attributable to the introduction of the modern system of progressive taxation. In the third place, we note the development of the idea of
f. faculty or ability to pay. More and more the system of taxation has been molded by the desire to fix the burden to the capacity of the contributors and the tests that have been progressively devised to measure that capacity, as will be seen below, undergone a continual modification. In the fourth place, side by side with the adoption of individual faculty we note the substitution of the social for the individual treatment of the element, that is, a system modified by a study of the social consequences and economic effects of the tax system upon the various economic classes in the community as a whole.

Influence and Effects of Taxation. — The effects of production. Here again two theories stand opposed to each other. A former school contended that taxes stimulate production. It had been claimed by some that a new tax evokes a new ability to bear the tax and that in this sense an increase in the seeming burden may really augment the industry of the people. It has been argued that if industry in general is the result of coping with the natural disadvantages, such as the inclemencies or difficulties of nature, why should not the same result be brought about in other ways, e.g., by taxation? Attention is directed to the period of the Napoleonic wars where the increase of British taxes seemed to result in greater power to bear the taxes. On the other hand, we find the contention that all taxes are injurious, or, as in the case of the Single Taxers, that all taxes excepting the land value tax exercise a deleterious influence because they are taxes on labor and industry and, therefore, check or retrograde the industry.

The truth again lies in the midway. It is undoubtedly a fact that some taxes seem to increase industry. But if regarded more attentively it will be seen that the tax is the occasion, rather than the cause, of the redoubled activity and in that almost all cases the lure of profit rather than the fear of loss is the real stimulus to productivity and invention. It is undoubtedly far more frequent that industry is injuriously affected, rather than benefited, by the tax. But it is true that every tax excites an injurious result. If certain principles of equality are observed, it is possible for a tax to be innocuous so far as the producer is concerned, and, at the same time, to have the consumer benefit more from the results of the government outlay than he suffers from the tax. There is no broad generalization to be framed in this respect. According to the character of the particular impost, taxation may be said to have educational, destructive or regenerative effects. There are two points of more general influence. One is connected with the inequality of taxation. If an exclusive or unequal tax is imposed upon some permanent source of revenue, the tax or the excess of the tax over the normal rate will be amortized or capitalized into the diminution of the selling value. If 1 per cent is assessed upon securities, for instance, which bear 5 per cent interest and have been selling at par, the new purchaser will pay only about 84 per cent. This is known as the capitalization of taxation. The same tendency of things to seek their level is found in the imposition of a new tax in general. A French writer, Duvergier, had laid down the principle that every new tax is a bad tax and every old tax is a good tax. What he meant was that the disturbance of industry by the imposition of a new tax often takes some time to allow this of course must not be misinterpreted. The belief that a tax which is inequitable, can ever become good through the lapse of time is marked. The chief reason, for it there is no large class of real estate. Parishes as compared with New York is a case in point of a system modified by a study of the social consequences and economic effects of the tax system upon the various economic classes in the community as a whole. The effect of taxation on exchange is the so-called price doctrine. In its original form it held that every time a tax was changed hands the tax grew in proportion, for as the profits of the are added to the price, the tax is added each case successively on the new price, increasing the profits. This alleged principle, ever, is open to the objection that according to modern economic theory, profits are not of price, but the result of price and the price is in turn set at a certain cost. The element of truth contained in this principle is due to the fact that interest part of cost and that to the extent that on the successive prices is of any importance the theoretical tax tends to be cumulative. The impact of taxation on distribution is indisputable. Taxes are designed to have such an effect as to high inheritance taxes, graduated income, but many taxes also have unexpected effects. A general and well-recognized maxim is "leave them as you find them" doctrine that the ideal tax ought to leave every individual in the same relative position as the imposition of the tax. This is not accepted as an ideal.

The influence of taxes on consumption is less important than in former times. In the Middle Ages a sumptuary tax was common. It was, however, not consumption, but necessary consumption was frequently sought to be hit by means with which taxes of certain kinds made to check consumption are so pronounced that it is primarily in periods of war that recourse is taken to this medium.

The political effects of taxation are important than the economic. The government itself has been influenced by the effects of taxation.

Incidence of Taxation. — By the term a tax is meant its final resting place, or its original assessment, the shifting of its transfer, and the incidence of a tax to its final resting place. Shifting is incidence is the result the tax is not always the one who pays in the first instance. This has led some to lay down the so-called equal-diffusion of taxation, the theory, namely, that economic is like any organism and that the tax will influence the community as a whole, it will at once be diffused throughout. The tax, therefore, no matter where it will be shifted to the community at large, the theory suffers from undue generalization. It is true that certain taxes give rise to such in economic relations that they may
o be ultimately spread over the com-
There are, on the other hand, many
which do not lead to this phenomena and
e which are not shifted at all. A dis-
ust furthermore be observed between-
tion and shifting. If a tax is shifted,
be capitalized; if it cannot be shifted.

c economy. The two co-
cept of taxation may be declared
nucity and efficiency. The
or harmlessness of a tax is a most desirable
tribute. All taxes, indeed, represent a burden
but, as has been pointed out above, certain
taxes have a far more destructive effect than
others. Other things being equal, the legislator
must choose the most innocuous tax. By the
efficiency of taxation is meant the capacity of a
tax to accomplish the desired result. Many
a tax is admirable in other respects, but can
be made to work in practice only with diffi-
culty. The present property tax, for instance,
in the United States is to-day no longer an
efficient tax. The ethical principles of taxation
are those of uniformity and universality. As
these are the most important, they will be dis-
cussed separately.

Uniformity or Equality of Taxation.—
By equality is of course not meant absolute
numerical equality, but relatively proportional
equality. Uniformity, in other words, means
relative uniformity. The question then arises
as to the relation involved. To what should
be to be uniform? In former times the answer was that the real
basis of taxation should be either the cost of
service to the government or the value of the
service to the individual. The more modern
theory maintains that taxes should be in some
relation to the faculty or ability of the indi-
vidual to pay. Much time has been spent upon
the problem of what constituted the real
elements of faculty. For a long time faculty was
stated in terms of capacity. By equality of
taxation there is meant an equality in the sacri-
ce imposed upon the individual. In more
recent times, however, emphasis has been put
upon another aspect of the problem. Sacrifice
has to deal with the phenomenon of parting
with one's wealth. It involves the question of
what is left for immediate consumption after
the tax has been paid. But economic life deals
not only with consumption, but with production.
When we come to consider the production of
wealth rather than the consumption of wealth
we are confronted by the facts of opportunity
or privilege in the amassing of wealth. A
man's ability to pay a tax, therefore, must be
considered not only from the point of view of
consumption but from that of production. In
other words, the two elements of tax liability are
privilege and sacrifice: the easier it is for a
man to make his money, the more ability he
has to pay taxes; the harder it is for a man
to be deprived of his money, the less ability
he has to pay taxes.

The Norm of Taxation.—By the norm of
 taxation is meant the test of faculty. There
have been no less than five such tests disclosed
in the history of taxation: (1) The first test of
faculty was poll. Everyone was supposed
to have an equal ability to pay. In a primitive
form of society the poll tax was legitimate.
It has virtually disappeared today except in
a few democratic communities like the United
States, where it still lingers as a survival of a
former and more primitive equality. (2) Ex-
penditure. The advantage of expenditure
is that is no one can escape because every-
one spends something. The disadvantage of
expenditure as a test of faculty is that
some people must spend all they make, while
others can save most of what they make. Ex-
penditure thus becomes an increasingly unsatis-
TAXATION

factory test of faculty; (3) Property. In a comparatively early form of society wealth in terms of property is an excellent test of faculty. The general property tax is accordingly found everywhere at a certain stage of development. The more complicated and the more differentiated the society, the more apparent, however, are the shortcomings of this test. The chief modern defects of property as a test of equality in taxation are the following: (a) While it is generally true that capital is nothing but capitalized income, there is in modern times frequently a discrepancy between the property and the yield or produce of the property. This may be due to speculation, to chance or to other accidents of economic life; (b) In modern times more and more wealth is derived from personal earnings rather than from property. The property tax would hit the owner of a $10,000 farm but leave untaxed the recipient of a $100,000 professional income; (c) There is a great difference between the legal and the economic value of property. Economically a man's wealth measured in terms of capital is his surplus over debts. Legally, property is independent of the debts. I may own a $10,000 farm even though I have borrowed $5,000 on it. A property tax frequently fails to make allowance for debts; (d) The concept of property fails to distinguish between consumption and production property. The property tax makes no distinction between the lawyer's library which contributes to his income and a philosopher's library which may be a source of expense. 4. Product. The difficulties with the concept of property as a test of faculty led to the substitution of yield or produce as the proper test. Almost everywhere at a certain time the general property tax on the individual was, therefore, replaced by a series of taxes on the things themselves, measured by their product. Instead of a general property tax we now find a land tax, a capital tax, a business tax, a wage tax, etc. Produce is in some respects a more satisfactory test of faculty than property: it gets closer to the realities. But in the course of time a weakness disclosed itself in that not enough attention could be paid to the individual conditions of the recipient of the income. The modern world has, therefore, come to large measure to an acceptance of the fifth test of faculty, which is that of income rather than of property or of produce. The tendency is accordingly stronger for the replacement of the older taxes by modern taxes on individual income and business profits.

Graduated Taxation.—A further refinement, however, of the idea of faculty is seen in the growth of graduated or progressive taxation. Proportional taxation is giving way to graduated or progressive taxation because of the realization of the fact that graduation, although a technical breach of uniformity, really involves a higher uniformity. Progressive taxation is now almost everywhere recognized even in American jurisprudence, as involving no inequality of taxation. A graduated tax is a tax the rate of which increases with every unit of the base. The entering wedge of the theory of progressive taxation is found in the minimum subsistence doctrine, the doctrine, namely, that a certain amount of income should be exempt from taxation because that is indispensable to existence. This was soon pushed further in so far as placed upon the element of sacrifice; the sacrifice involved in taking by taxation a man with a $1,000 income was less than the sacrifice involved in taking $10,000 from the man with a $100,000 income. In one case the tax trenches on necessities and in the other it affects superfluities. After some time, however, conception of sacrifice was re-enforced by privilege. The difficulty of making $1,000 of a man's fortune is far less that of making subsequent accretions. Modern democracies are accordingly fixing a graduated or progressive tax.

Differentiated Taxation.—The principle in taxation results not only in graduated taxation but in what is called differentiated taxation. Graduated taxation implies a change in the rate according to the amount of income or property. Economically, a man's wealth measured in terms of capital is his surplus over debts. Legally, property is independent of the debts. I may own a $10,000 farm even though I have borrowed $5,000 on it. A property tax frequently fails to make allowance for debts; (d) The concept of property fails to distinguish between consumption and production property. The property tax makes no distinction between the lawyer's library which contributes to his income and a philosopher's library which may be a source of expense. 4. Product. The difficulties with the concept of property as a test of faculty led to the substitution of yield or produce as the proper test. Almost everywhere at a certain time the general property tax on the individual was, therefore, replaced by a series of taxes on the things themselves, measured by their product. Instead of a general property tax we now find a land tax, a capital tax, a business tax, a wage tax, etc. Produce is in some respects a more satisfactory test of faculty than property: it gets closer to the realities. But in the course of time a weakness disclosed itself in that not enough attention could be paid to the individual conditions of the recipient of the income. The modern world has, therefore, come to large measure to an acceptance of the fifth test of faculty, which is that of income rather than of property or of produce. The tendency is accordingly stronger for the replacement of the older taxes by modern taxes on individual income and business profits.

Graduated Taxation.—A further refinement, however, of the idea of faculty is seen in the growth of graduated or progressive taxation. Proportional taxation is giving way to graduated or progressive taxation because of the realization of the fact that graduation, although a technical breach of uniformity, really involves a higher uniformity. Progressive taxation is now almost everywhere recognized even in American jurisprudence, as involving no inequality of taxation. A graduated tax is a tax the rate of which increases with every unit of the base. The entering wedge of the theory of progressive taxation is found in the minimum subsistence doctrine, the doctrine, namely, that a certain amount of income should
Ordinarily, to tax property is virtually to tax the income of the property. To come again will then be double taxation. It serves no purpose to distinguish between earned or unearned incomes or to separate taxation, where in other cases it is to tax property incomes; other incomes, that form of double taxation is legitimate. Another example of taxation is to tax the corporation and its shareholder or to tax both the property and the income, because ordinary conditions of American life are expensive and the lender will be shifted to the borrower who will pay the tax on his own property but on that of others. Double taxation by competing jurisdictions is found when the same individual owns property is simultaneously taxed by jurisdictions. The tax is on the same property and the same property. The avoidance of such double taxation is possible. The one international agreement or the exerts may be taxed on the same property in all states. The avoidance of such double taxation is possible either, on the other hand, the separate property taxes gradually developed into a general property tax, which became the chief source of state and local revenue. The tax was being added to the local tax in the public before the annual rate of taxation was determined. With the progress of society and especially with the growth of intangible personality, personal property slowly slipped out of the assessment lists, so that the general property tax again became in fact, if not in law, a real property tax in great measure. This led, in the third quarter of the century, to an attempt to tax personal property through special taxes on certain corporations. Toward the close of the century the corporation taxes were supplemented by inheritance taxes. In several States liquor license taxes were added. Only in the Southern States do we also find a system of business or occupation or so-called privilege tax at a survival of the Slavery system, where the plantation owners attempted to roll off the taxes on urban occupation.

The addition of corporation and inheritance taxes did not entirely solve the problem of the personal property tax. A two-tiered system of tax accordingly developed in the 20th century. On the one hand we find the tendency toward the classification of personal property tax, with lower rates for certain classes of personality like money, securities, mortgages, etc. On the other hand came the movement for the replacement of the personal property tax by the income tax. Wisconsin took the lead in 1911, Massachusetts followed in part in 1915 and New York imposed a corporate income tax in 1916 and a personal income tax in 1919. Several other States have followed their example. The trend is now strongly toward a system whereby real estate will be taxed for local purposes and the State revenues be derived from an income tax, an inheritance tax and a corporation tax, part of the proceeds of which will be distributed to the local divisions.

The Federal tax system has also gone through several stages. At the beginning the Federal revenues were derived from import duties as well as from a variety of internal excises — including for a short time a direct tax on land and on slaves. The advent to power of the Anti-Federalists in 1802 caused an abandonment of the so-called internal reve-
TAXIDERMY

The art of stuffing and mounting the skins of animals, or their heads, so as to appear natural and lifelike. It is no longer a question of filling out a skin, but rather of making a statue of a creature long since dead, which will exactly fit the skin of that particular creature, stand erect and pose as the counterpart of life. "Taxidermy, the handmaid of zoology," said Dr. J. A. Allen, "has already become one of the fine arts, requiring the skill and judgment of both the sculptor and the painter, and capable of yielding results comparable with the masterpieces of either."

It is, furthermore, one of the newest of the arts and there is serious need of a well-established school of taxidermy in connection with some one of our great museums. Prior to 1880, one American museum (the National) maintained a corps of taxidermists, but not a single one. The majority of the mounted birds and mammals which found their way into other American museums were mounted at Ward's Natural Science Establishment, by men from France and Germany. Methods were crude and if anything were far below the standards attained twenty-five years later. Much of the work produced to 1880 has since been either dismantled or destroyed.

In March 1880, at Ward's establishment in Rochester, N.Y., Messrs. Hornaday, We Lucas, Martens, Bailly, Critchley and F. E. organized the National Society of American Taxidermists and seriously began the task of developing taxidermy up to the level of fine arts. All jealousy and exclusiveness were swept aside and the three competitive sections that were held in Rochester, Boston and New York finally opened the eyes of men and of the general public also to the possibilities of scholarly taxidermy, when the early impetus then gained has already carried American taxidermy beyond the original hopes of the founders of the society and the museums.

In Europe, America is now being filled with monographs that in large measure are not of real educational value but are also agreeable to the eye. No modern American museum now complete without a well-equipped department of taxidermy, in charge of a chief taxidermist on a salary, which in 1880 would have been considered unattainable.

In a modern, high-class taxidermist, the requisite is not a knowledge of methods mounting, but the thorough education of the eye in animal forms and expressions, must be secured by courses in drawing, painting and carving. The skeleton, external muscles of animals must be studied, the latter from life. Besides the ingenuity of numberless sketches from life, but of live-animal photographs should be considered. Care in arranging and arranging for reference. Casts of and special parts of dead animals are of importance and should be diligently collected. At all times must the natural history of the vertebrates be studied and kept in mind. This preparatory work has been accomplished, the aspirant for taxidermic honors must have admission to the laboratory of some master and work with him to acquire knowledge of methods.

A comparison of American with European taxidermy is of but passing interest, chiefly owing to the reason that an international exhibition it is impossible to draw parallels from the study of one's own work. From three inspection European zoological museums, 1896 and 1902, it is the opinion of the writer that the best of our museum taxidermy is considerably in advance of the best to be found in Europe. The groups of mammals, especially small, that now are so intensely interesting with the zoological gardens and parks of New York, Pittsburg, Chicago, Milwaukee and the University of Kansas, have no counterpart in Europe. The British Museum of Natural History, South Kensington, contains a series of groups of birds, mounted with
es. In the museum of the Amsterdam Artis Magistra, there are a number of groups of birds. In the museums American cities mentioned above the fly groups representing the bison, caribou, musk-ox, deer, antelope, zebra and other animals, all provided fully-studied natural accessories, condoning monuments to the skill of museum officers who have actively the development of American taxi-Pro. Spencer F. Baird and Dr. G. Soodey stand first. As early as 1880 located the attainment of perfection in regardless of time or cost. It was by sent and cooperation that the National set the pace in the development of setups of mammals, which really began with the group of American bison. Section honorable mention is due Prof. A. Ward, founder of Ward's Natural Establishment, for the far-reaching inserted by him for the improvement of methods generally and the company which is now appended to the Society of Taxidermists.

The improvements noted in museum, equal advances have been made in of what is known as custom taxidermy. Iber of trophy heads of large mammals now mounted annually in the United States are less than about 1,800. About 40 are heads of deer and the remainder moose, mountain-sheep, caribou, elk, mountain-goat, buffalo, musk-ox and out in the order named. Twenty-five to a finely-mounted head was a rarity, any, outside of the workshops of amably-mounted head is seldom seen. Standards of excellence have risen very. The demands of patrons are more in and good work is better compensated eto fore.

The world's mammals, birds and other decreases, museums multiply, and the provision fine collections becomes more and more urgent. New York now offers a 11 for a limited number of young men artistic instincts who can bring to it education and training and unlimited for hard work.

Important American works on taxonomy should be enumerated: Hornaday, "Hornaday, Taxon: and Zoological Collecting" (1892); "Methods in the Art of Taxidermy" Rowley, "Art of Taxidermy" (1900); K., "Guide to Taxidermy" (Worcester.

W. T. HORNDAY,
Director New York Zoological Park.

TAXING DISTRICT. See DISTRICT.

XYONYM IN PLANTS, from the Greek words παίζει ταξινομείν, meaning and nomen, nomos, law. Called taxonomy. It is the study of class, especially from a biological aspect, and of the morphology of plants. Life. Ray divided the vegetable kingdom into two classes: the Flowering and the Flowering everything on one single character, a little over a century later, formed the plant world into two groups: Cormophya and Thallophyta, but the division was very imperfect and overlapping. Later we found two groupings by Linnaeus under the names: Phanerogamia and Cryptogamia, the former having flowers with stamens and pistils, the latter flowerless, seedless and propagated by spores. But the designation Cryptogamia, still retained by a few, their generative method being no longer cryptic (occult) or hidden from our present advanced knowledge. Thallophyta, still remaining in general use, no longer describes the class formerly considered by the expression. Thus with ever-increasing knowledge of the life-workings of the plant realm bringing new facts we have had to change repeatedly the system in taxonomy to bring the additional facts into close relation. And so the system of Ray gave way to the Endlicher, the latter to the greatly improved system of Linnaeus (1735) with its 24 classes divided according to the number and disposition of the stamens, with variant orders according to the number of styles or stigmas, etc. This method of systematization, proving its deficiencies more with a deeper investigation of plant nature, had to give way (1813) to the Candolle system, soon to be displaced by the Sachs method of classification with its seven divisions, Protophyta, Zygo phyta, Oophyta, Caryophyta, Bryophyta, Pteridophyta, Phanerogamia. The Sachs system is much in use to this day, but the most recent classification of botanists, based on the great advances brought about by microscopic and other researches into the plant structure, which keep disclosing weaknesses of the former system, are the following four main classifying divisions: (1) Thallophyta; (2) Bryophyta; (3) Pteridophyta; (4) Spermatophyta. The first three belong to the Cryptograms, the latter to the Phanerogams. It is an improvement generally considered better suited to the enlarged range of the botanist's vision; but already criticism is creeping in and taxonomy in plants may be subjected soon authoritatively to a further revision.

(1) Thallophyta. This division includes all of the four primary classes, the uni-cellular organic growth, having root, stem and leaf undefined. Under this head come the algae, fungi, bacteria and lichens. (See BOTANY).

(2) Bryophyta. These include the mosses and liverworts (hepatica), with distinct sexual organs in some, but in this division (as above stated) is the liverwort and other plants of the thallus type. (See BRYOPHYLLUM). (3) Pteridophyta. These are often termed vascular cryptograms and include chiefly the ferns with their propagation by spores. Their stem, leaf and root are clearly defined. (See PHANEROGYTA). (4) Spermatophyta or Phanerogams. These are being lately divided into angiosperms and gymnosperms and the angiosperms are sub-divided into dicotyledons and monocotyledons. The Spermatophyta are the highest division of plants including those having true flowers and seeds. They are for the most part land plants, while many of the former divisions are aquatic. Their female cell (oospore) is fertilized in propagation and, protected by the ovule, becomes a seed, the seed formation being the characteristic of this group (termed also seed-
TAY—TAYLOR

plants). (Gymnosperms of this division have
unsewelled flowers and naked ovules, with direct
pollen fertilization, etc. (See GYMNOSPERM.).
Angiosperms have a closed seed vessel (carpel)
and other distinguishing characteristics. See
PLANTS, CLASSIFICATION OF.

TAY, tā (1) A river in Scotland, in the county of Perth, formed by two head-streams, the one rising from the northeast end of Loch
Tay and the other from Loch Lyon, a small
lake on the borders of Argyllshire. The two
streams unite about two miles northeast of
Loch Tay, whence the river flows past Aber-
feldy, Dunkeld and Perth, at which last town
it widens out into an estuary from one to three
miles in breadth, becoming the northern bound-
ary of the county of Fife. The whole length is
120 miles and the area of basin 2,250 square
miles. Vessels of 500 tons ascend to New-
burgh and those drawing nine feet to Perth.
Its principal tributaries are the Tummel and
Isla on the left and the Braan, Almond and
Earn on the right. During the upper part of
its course Tay flows through a wild and highly
romantic country and subsequently, after entering Strathmore, through the richest and finest valley in Scot-
land. In the summer of 1878 a railway bridge
spanning the estuary of the Tay at Dundee was
opened for traffic, but on 28 Dec. 1879 13 spans,
crossing the navigable part of the river, were
blown down in a violent storm, a passenger
train, which then happened to be crossing, be-
ing precipitated at the same time into the river.
A second bridge, over two miles long, with 85
spans and carrying two lines of rail, was
opened in 1887. (2) A loch in the county of
Perth, a picturesque sheet of water 15 miles
long and about one mile broad; receiving at its
southwest end (near Killin) the Lochay and
the Dochart and discharging at its northeast
end at Kenmore by the Tay. It is 100 to 600
feet deep and is well supplied with fish.
On its northwest shore rises Ben Lawers.

TAYABAS, tā-yā bahs, Philippines, (1) Puente Extender of Tayabas; on Tayabas River,
five miles inland, 65 miles southwest of Manila.
Under Spanish jurisdiction it was the capital of
the province, and is the largest town. It is
an important road centre and carries on a
large trade. Pop. 15,000. (2) Province, form-
ing the western part of southern Luzon; bound-
ed on the north by the Pacific Ocean, and
Lamón Bay and Ambos Camarines, on the east
by Ambos Camarines and the Visayan
Sea, on the south by the Mindoro Sea, and
on the west by Batanacan and Lomaca; area,
about 5,000 square miles. The outline is very
irregular; its extreme length from Point Piapi
in the northwest to Point Paseanjan in the
southeast is 102 miles; and the distance from
the northeastern boundary to Soudal Point
on the southwestern coast is 57. Its coasts are
indicated by three of the largest bays of the
Philippines, Lamón on the north, Raday on
the east and Tayabas on the south. The province
is generally mountainous, the main central
chain being mountainous and this range extends
out spurs on each side. There are numerous small rivers and streams.
The soil of the valley is fertile; on the lower
levels rice, sugar and coffee are raised and
grain on the higher levels; a special product
is a seed called lumhang from which
may be made; the coastline is crowded in large.
ities. The forests contain a variety of
for building purposes, besides gum and
trees; and large quantities of timber and
products are exported. The mechnical
tries of this province are of considerable
importance; the manufactures include hats,
cases and boxes and native fashions; the
also mills for extracting coconut oil.
number of boat-building yards for the
struction of native boats. Stock-ra
also of some importance. The provi
good communication by water with all
the Philippines, and is traversed by a
highway from Sorosogon to Manila; the
also several other roads and trails.
The Itans of the western part of the provin
Tayabas, those of the eastern part are
Civil government was established in
1901, in accordance with the law of the
pine Commission. Pop. about 150,000.

TAYGETUS, tā-jē tūs, Greece, a
chain range running down the central part
of southern Mores. It is a steep and un
ridge rising in Hagios Elias to a be
7,904 feet. It separated an area of
Messenia and was known in the Middles
as Pentedakylon.

TAYLOR, tā lōr, (James) Bayard, J
can writer: b. Kennett Square, Pa., 1
1825; d. Berlin, Germany, 19 Dec. 1877
had a secondary education at West Chest
Unionville, and in 1842 was appointed to
printer in the former town, but did not
out his apprenticeship. In 1844 he set
Liverpool, and during the next two years
traveled, chiefly on foot, in Great Britain,
Germany, Austria, Italy and France.
described his journeys for several Am
newspapers, his letters being collected an
lished on his return under the title 'A
foot or Europe Seen with Knapsack
Staff' (1846). In 1847 he received an
ment on the staff of the New York 'Times
and two years later went to California
special correspondent of that newspaper
old-fields, his letters being republ
1850 as 'Eldorado, or Adventures in
of Empire.' In 1851 he was again in E
before returning to the United States.
1854 he visited Egypt, Asia Minor, India,
ong, China and Japan. Among the
results of this tour were 'A Journey to
Africa' (1854); 'The Land of the Sa
(1854), and 'A Visit to India, China
Japan' (1855). On these traveling expedi-
he lectured with much success. He had a
time gained some reputation as a

OR, Charles Henry, American jour-
Boston, 14 July 1846. He made
instructor and reporter private secretary to the government of
etts for three years. He served dur-
War with the 38th Massachusetts
and was lieutenant-colonel on the
orner Claffin. He was member of
the legislature in 1872, and in 1873 became
manager and editor of the Boston Daily Globe. He built up the property and made it one of
the most influential journals of New England.

TAYLOR, Charles Jay, American artist:
b. New York, 11 Aug. 1853. Attended College
City of New York, afterward graduated at
Law School, Columbia University (1874),
LL.B., subsequently studied art, National
Academy of Design, Art Students League
in London and Paris. Has illustrated many books,
contributed drawings to prominent periodicals
and exhibited at the National Academy of
Design, Pennsylvania Academy of Fine
Arts, World's Fair, Chicago; Exposition Universelle,
Paris; Pan-American, Buffalo, where awarded
medal; Carnegie Institute, Pittsburgh, and at
Panama-Pacific Exposition, San Francisco.
He served on advisory committee on Fine
Arts for the Panama-Pacific, representing
Pennsylvania; also was one of the Inter-
national Jury of Awards, Section of Fine Arts,
for the same exposition. From 1911, pro-
essor of fine arts, Carnegie Institute of
Technology, Pittsburgh.

TAYLOR, David Watson, American naval
constructor: b. Louisa County, Va., 4 March,
1864. He was graduated at the United States
Naval Academy in 1885, with the highest rec-
cord ever made there. At Greenwich, England,
in 1885, he received the highest honors of the
Royal College, repeating the record in 1886.
He was made captain, United States navy, in 1901
and, by 1917, was promoted to rear-admiral.
In 1914 he became chief constructor of the
United States navy and chief of the Bureau of
Construction and Repair.

TAYLOR, Edward Thompson, American
Methodist missionary: b. Richmond, Va.,
December 1793; d. Boston, Mass., 6 April 1871.
At the age of seven he ran away to sea, and
followed the sea until the age of 17. During
the War of 1812 he was captured on a priv-
eteer of war, the Black Hawk, and was taken
to England, being confined in Dartmoor prison.
Being converted, he acted as chaplain in
the prison and after his release, for a time was a
tin and iron peddler, then a buyer of rags and
a farmer. In 1819 he became a Methodist
minister, and in 1828 was appointed missionary
to the Seamen's Bethel in Boston, where he
served for many years, attaining a wide repu-
tation. Here he was called 'Father Taylor' and
was greatly loved by the sailors. In his ser-
mons, which he delivered in the common lan-
guage of his day, he made free use of nautical
terms, and possessed a genial wit. In 1832 he
visited Europe, and delivered many addresses.
In 1842 he visited Palestine, and was chosen
chaplain of the United States frigate Macedonia,
then he sailed with relief in 1846 for the istric
Ireland. Consult 'Father Taylor the Sailor Preacher' (1872).

TAYLOR, Sir Frederick Williams, Cana-
dian financier: b. Moncton, New Brunswick,
1863. He entered the Bank of Montreal
in 1878, becoming successively assistant in-
spector at head office (1897), joint manager of
the Chicago (1903), manager of London branch
(1906), and general manager at Montreal
(1913). He carried through huge banking
loans to Canada during his London services.
He is a director of the Allen Line Steamship Company, Ltd., vice-president of the Canadian Bankers’ Association, etc. For valuable services he was knighted in 1913.

**TAYLOR, Frederick Winslow**, American efficiency engineer: b. Germantown, Pa., 20 March 1856; d. 21 March 1915. Educated at Phillips Exeter Academy, but left on account of eyesight trouble, and was graduated (1883) at Stevens Institute of Technology. In 1887 he entered service at the Midvale Steel Company, Philadelphia, becoming, successively gang-boss, assistant foreman, foreman of machine shop, master mechanic, chief draughtsman and (1889) chief engineer. In the latter year he commenced his notable career of efficiency expert, reorganizing manufacturing plants (shop accounting and sales departments) of which the Bethlehem Steel Company, Cramps Shipbuilding Company, etc., were examples. He was the inventor of the Taylor White process of treating modern high-speed tools, receiving a personal gold medal at Paris Exposition, 1900. Patents granted to him number over 100. He was president of the American Society of Mechanical Engineers, 1905-06. He wrote: *Concrete, Plain and Reinforced* (1905); in collaboration with S. E. Thompson; *Art of Cutting Metals* (1905); *Principles of Scientific Management* (1911); *Shop Management* (1911), and contributed numerous articles on his special topic to *Proceedings of American Society of Mechanical Engineers*.

**TAYLOR, George**, American statesman, one of the signers of the Declaration of Independence: b. Ireland, 1716; d. Easton, Pa., 23 Feb. 1781. Disliking the medical profession, for which he was destined, he came to America as a "redemptioner," and on arriving bound himself for a term of years to an iron manufacturer at Durham, Pa. His education and intelligence being discovered, his employer made him his clerk, and after his death Taylor married his widow and became master of the establishment. He was a member of the provincial assembly in 1764-70, when he was a judge of the County Court and colonel of militia. In October 1775 he was again elected to the provincial assembly and was active in the promotion of revolutionary measures. The action of some of the members of the Continental Congress the next year in refusing assent to the Declaration of Independence, led to the election of new members, 20 July 1776, of whom Taylor was one. He signed the Declaration on 2 August; subsequently negotiated a treaty with several of the Indian tribes on behalf of the United States, and in March 1777 retired from Congress to private life.

**TAYLOR, Graham**, American sociologist: b. Schenectady, N. Y., 2 May 1851. He was graduated (1870) at Rutgers College and at the Reid Theological Seminary, New Brunswick, N. J., in 1873. He was ordained for the Dutch Reformed ministry in 1873, becoming pastor at Hopewell, N. J. From 1880-92 he filled the pulpit of the Fourth Congregational Church, Hartford, Conn. He acted as professor of practical theology at the Yale Theological Seminary from 1888-92, and, since 1892, has served as professor of social economics at the Chicago Theological Seminary. He was founder of the Chicago Commons Social Settlement, which has been resident warden since 1894. He was president of the Chicago School of Civics and Philanthropy and associate editor of *The Survey*. He has written *Religion in Surgery* (1913), besides numerous editorials to *The Chicago Daily News*.

**TAYLOR, Sir Henry**, English poet: b. Bishop-Middleham, Durham, 1800; d. Bournmouth, 28 March 1886. He entered the navy as midshipman, turned after a few months. In 1817-20 he had a small appointment in London. Returning to his father’s country home, he gave himself to serious study, and in 1822 wrote an art for the Quarterly Review. He went to London, and received a clerkship in the Colonial Office, through which he retained his connection for 48 years. He mingled with the intellectual life of the times, contributed to the Quarterly Review, wrote his first tragedy, *Isaac Comenius* in 1827. He was favorably reviewed by *Sartor Resartus*, but failed to attract popular notice. From 1834 he was engaged upon another drama, *Philip van Artevelde*, his principal achievement in literature. It was formed *Elizabethan* models, and has *Mephistophelian* dignity and refinement. His other works include *The Statesman* (1836), *Klopstock* (1835), *Notes upon the Poems* (1847); *Notes from the Virgin Widow* (1847); *A Sicilian Summer* (1850); *Saint Clement’s Eve* (1862), a *koom* drama. His autobiography was published 1885. Consult his *Works* (1878), and *response*, edited by Dowden (1888).

**TAYLOR, Henry Ling**, American geologist: b. New York, 17 March 1837. He graduated (1877) at Sheffield Scientific School and obtained his diploma at the College of Physicians and Surgeons (Columbia) in 1881. His father, Charles Fayette Taylor, specialized on orthopedic branches and was a professor of orthopedic surgery (1902-1907) at the New York Medical School and Hospital. He is consulting orthopedic surgeon at Hartford Hospital, and associate surgeon at the Hospital for Ruptured and Crippled. He was president of the American Orthopaedic Association in 1890.

. In the latter year he becam
in London, and in 1864 published the
works by which he is chiefly re-
'Words and Places, or Etymologi-
cal Illustrations of History, Ethnology and
 Geography.' In 1869–73 he held a curacy in
a Bethnal Green parish, and his arduous labors
there are described in 'The Burden of
Poor.' He became vicar of Holy Trinity,
Twickenham, in 1869, and in 1875 was pre-
sented to the rectory of Settington, near Mal-
ton, in Yorkshire, which he retained until his
death. In 1879 he first propounded the theory of
the Greek origin of runes in a work entitled
'Greeks and Goths: A Study of the Runes';
and he published in German a treatise 'Ueber
den ursprung des slavischen Alphabetes,' but
his magnum opus, 'The Alphabet: An Account
of the Origin and Development of Letters;' did
not appear until 1883. In 1885 he was appointed
of York. His other works include 'The
Family Pen: Memorials, Biographical and Lit-
erary, of the Taylors of Ongar' (1867);
'Etruscan Researches' (1874); 'Leaves from
an Egyptian Note-Book' (1888); 'The Origin
of the Aryans' (1889); and 'Names and their
Histories: A Handbook of Historical Geogra-
phy and Topographical Nomenclature' (1896).

TAYLOR, Isaac Ebenezer, American phy-
 b. Philadelphia, 25 April 1812; d. New
 York, 30 Oct. 1889. He was graduated
 from Rutgers College in 1830, and in medicine
from the University of Pennsylvania in 1834. He
subsequently studied in Europe, settled in New
York, and had charge of the department of
women's diseases at the City, Eastern, and De-
ern and Demitt dispensaries for seven years
each. In 1851 he was elected physician to Bel-
vue Hospital, where he initiated important re-
forms, secured the foundation of the hospital
college, and became its head, 1861. He was
subsequently president of the medical board
of the hospital; attending physician and head
of the medical board of the Charity Hospital,
and obstetrical physician to the Maternity Hos-
tial. He was the first American to introduce uterine
consolation, helped introduce the hypodermic
method of treatment by morphia and strychnia,
and was the earliest in this country to use the
speculum in diseases of women and children.
He published a monograph on this subject in
1841.

TAYLOR, James Knox, American archi-
b. Knoxville, Ill., 11 Oct. 1857. He took a
special course (1877–79) in architecture at the
Massachusetts Institute of Technology, then
served in New York architects' office three and
a half years. From 1882–92 he practised in
Saint Paul and at Philadelphia from 1892–1905.
In 1895 he was appointed senior draughtsman at
the United States architect's office and
then, till 1897, principal draughtsman. From
1897–1912 he was supervising architect and since
1912 has been director of architecture at the
Massachusetts Institute of Technology, Boston.

TAYLOR, James Munroe, American edu-
cator: b. Brooklyn, N. Y., 5 Aug. 1848. He was
graduated from the University of Rochester
in 1868 and was pastor of a Baptist church in
South Norwalk, Conn., 1873–82, and at Provi-
dence, R. I., 1882–86. In 1886 to February
1914 he was professor of ethics and president
of Vassar College. He has published 'Psy-
ology' (1893); 'New World and Old Gospel'
(1900); 'Practical or Ideal' (1901); 'Before
Vassar Opened’ (1914); ‘Vassar: A History’ (1915).

TAYLOR, Jane. English poet and author, daughter of Isaac Taylor, 1759–1822, (q.v.), b. London, 23 Sept. 1783; d. Ongar, Essex, 12 April 1823. She was educated under the supervision of her father and early displayed literary ability. Her work, which was very suc- cessful, has been much brought to the notice of Cowper. Her first work was ‘The Beg- gar Boy’ (1804) and in conjunction with her sister Ann (Mrs. Gilbert, of Nottingham, 1783–1824), she published ‘Original Poems’ and ‘Hymns for Infant Minds’. Her other work includes ‘Display’, a didactic tale (1815); ‘Essays in Rhymes’ (1816), and (published posthumously) ‘Contributions of Q. Q. to a Periodical’ (1826); ‘Correspondence’ (1825), etc. Consult Taylor, Isaac, ‘Memorials of the Taylors’ Family’ (1871).

TAYLOR, Jeremy, English prelate and author; b. Cambridge, 1613; d. Lisburn, County Antrim, Ireland, 13 Aug. 1667. After graduation in 1630 from Caius College, Cambridge, he was ordained in 1634, attracted some attention lectures at Saint Paul’s School, and was sent by Laud to Oxford, where he was admitted perpetual Fellow in 1636. He was presented to the rectory of Uppingham, Rutland, in 1638, to that of Overstone, Northamptonshire, in 1643. By this time he had made much of a reputation by his casuistical discourses. In the civil war he was committed to the Royalist party. As chaplain in ordinary to the king, he accompanied the army and was taken prisoner by the Parliamentarians in the battle before Cardigan Castle (1645). Soon released, he remained in Wales, having found, as he later said, that the ‘great storm’ had ‘dashed the vessel of the church all in pieces.’ While chaplain to Richard Vaughan, Earl of Clarcy, at Golden Grove, Carmarthenshire, he did some of his best literary work, including ‘The Liberty of Prophecying’ (1646); ‘Holy Living’ (1650), and ‘Holy Dying’ (1651). He was twice imprisoned at Chesham, and occasions preached to small Presbyterian congregations in London and in 1658 was appointed to a weekly lectureship at Lisburn, County Antrim. In April 1690 he signed the ‘declaration’ of the Loyalists and in August following he was made bishop of Down and Connor. He found the troublesomeness of the Presbyterians, who refused to recognize Episcopal jurisdiction. At his first visitation he declared 56 churches vacant, their incumbents not having been episcopally ordained. Contrary to his pur- pose, he contributed greatly toward the establish- ment of Loyalist Presbyterians in northern Ireland as an independent ecclesiastical organization. Of his works, the best known is probably the ‘Liberty of Prophecying’—by which he meant expounding—a defense of toleration. He rests this plea for private judgment the uncertainty and inadequacy of tradition, the fallibility of any arbiter that may be selected on account of controversy, and the diffi- culty of expounding the Scriptures. Coleridge thought the result of the argument was that ‘so much can be said for every opinion and sect’ that appeal must be made to some positive jurisdiction on earth.’ Perhaps Taylor’s was merely a ‘legal settlement.’ At it is otherwise inconsistent with his work in Ireland. But he was at his best accurate theologian or polemistr as but as of righteousness. His literary work, generally thought to be seen in his sermons. They do not lack — redundancy, diffuseness, a love of quotation and illustration; they were always eloquent, with a certain vivi- nity and solidity for which many have been unable to find an equal. His devotional works, inspiring fori- ney, are also highly valued by his followers. Next to the ‘Liberty of Prophecying’ and now the most widely read are collected editions by Bishop Heath (22) and by Eden (1847–54). (See 1: 177; 22: 186.)

TAYLOR, John, English poet; b. Hertfordshire, 24 Aug. 1580; d. London, 1653. When young he was taken to Oxford and apprenticed to a waterman, henchman of the ‘water-poet,* by which he is known. He was at the taking of the Earl of Essex, in 1596, and afterwards in Germany and Scotland. At home he was years collector for the lieutenant of Oxford, and his fees of the wines and the ships which were captured. When the civil war broke out he lived in London, where he kept a common house, and wrote pasquinades upon the heads. He afterward kept a public house near Westminster. Certain of his works were published under the title ‘All the Works of Taylor, the Water-Poet, being Sixty and Number, collected into one volume;’ revised, and new parts added (1618). They were subsequently increased to 130, a very large number. They are not of natural humor and of the jingling prevails so much during the reigns. It as a mirror of the coarse manners of the times they are invaluable to the history of antiquity.

TAYLOR, Joseph, a high priest by Joseph 1832 and in 1882 went as a Mormon to various parts of the British Isles. Thy thing he returned and settled at III, where in 1844, in company with other Mormon leaders, charges of disloyalty were brought against Carthage jail where the prisoners were attacked by a mob, two of them were killed and he was
TAYLOR

uring from a second mission to 46 he went to the new Mormon Salt Lake City and in 1849 was licute judge of the Mormon State. He subsequently translated and 'Book of Mormon' in French. In 1854 he was elected a mem- ber of the legislature on New York, published 'The took charge of Mormon follow- yst. From 1877 to 1880 he was the Twelve Apostles and in the signed the first presidency and the and took the chief place himself. He was among those indicted grand jury under the Edmonds naineed in concealment until his

, John Louis, American jurist: England, 1 March 1769; d. Raleigh, 2 Nov. 1829. Arriving in this country in 1804 he gained an education at Mary College, Virginia, and was bar after reading law with- fe general and Fayetteville and be- fore the legislature (1792-95). Sworn (1796) he was appointed of the Superior Court, a posi- for 20 years, being chief justice he time. In 1821 he was elected ied justice of the Supreme Court of Alabama. He was appointed (1817), Judge Henry Potter, to revise the work 'Potter's Revival' of the Constitution of the State, which caused the work 'Potter's Revival' to be known as 'Taylor's Revival.'

, Mary Inlay, American novelist: D. C. She has published 'Lover'; 'A Yankee Vole'; 'The Cardinal's Musketeer'; 'Cobbler of Nimes' (1900); 'Little Mistt; Good' (1901); 'The Rebellion of the Red Staircase' (1900); 'The Reapings' (1908); 'Caleb Fich'; 'Long Way' (1913). She is also author of the photoplasys, 'The Ploughing Wilson'; 'Daughter,' etc.

, Nathaniel William, American clergyman: b. New Milford, e 1786; d. New Haven, Conn., 10 May 1876. He was graduated at Yale in 1823 and later became the pastor Congregational Church at New high position he continued until he resigned to become professor of 'ale. This chair he held during his life. He maintained the theology, especially on the tality of depravity, which was regarded led him into a controversy with the al branch of the Congregational 8-30. His works were edited and Noah Porter (1858-59).

, Philip Meadows, English mili- tary author: b. Liverpool, 28 Sept. ston, France, 13 May 1826. He tizan's army in India in 1824 and in 1841 was made administrator of the state of Shorapore, subduing its rebellious ruler. He rendered valuable service in keeping order during the berar mutiny in 1857, for which he was promoted to the rank of colonel. He published 'Confessions of a Thug' (1839); 'Tara' (1863); 'Ralph Darnell' (1865); 'Manual of the History of India' (1870); 'A Noble Queen' (1878), and other works. His autobiography was published in 1877.

TAYLOR, Richard, American soldier, son of Zachary Taylor (q. v.): b. New Orleans, La., 27 Jan. 1826; d. New York, 12 April 1879. He was graduated from Yale in 1845, after which he went to his father's camp on the Rio Grande and was present at Palo Alto and Resaca de la Palma. He sat in the Louisiana senate in 1856-60 and was a member of the Louisiana Seces- sion Convention. He aided in the organization of the Confederate troops, commanded a brig- ade under Stonewall Jackson and fought at Front Royal, Middletown, Winchester, Stras- burg, Cross Keys, Port Republic and also in the seven days' battle before Richard. He was then promoted major-general and appointed to the command of Louisiana, where he suc- ceeded in strengthening the Confederate posi- tion, an advantage which was lost by the fall of Vicksburg in 1863. On 8 April 1864 he met and defeated General Banks at Sabine Cross Roads, but on the following day lost his advantage and was in his turn defeated. He was pro- moted lieutenant-general in 1864 and placed in command of the Department of Alabama and Mississippi. After the surrender of Lee and Johnston he capitulated to General Canby at Citronelle, 8 May 1865. He published 'Destruction and Reconstruction' (1879).

TAYLOR, Robert William, American physician: b. London, England, 11 Aug. 1842; d. 1908. He was graduated at the College of Physicians and Surgeons, New York (1868) and started practice in that city. He was professor of diseases of the skin at Woman's Medical College, New York, and in the medical department of the University of Vermont; also surgeon in the venereal department of Charity Hospital, Bellevue Hospital, New York Dispensary, etc. He wrote 'A Practical Treatise on Sexual Disorders of the Male and Female' (New York, 3d ed., 1905).

TAYLOR, Rowland, English martyr: b. Rothbury, Northumberland; d. Hadleigh, Suffol, 9 Feb. 1555. He was graduated at Cam- bridge University and appointed by Cranmer, to whom he was domestic chaplain, rector of Hadleigh and he became archdeacon of Exeter and a canon of Rochester. Under Mary he was imprisoned, as a heretic, for more than a 12-month and on being condemned to the stake suffered at Hadleigh. Consult Cooper, 'Athenæ Cantabrigienses' (1858).

TAYLOR, Thomas, English scholar: b. London, 15 May 1758; d. Walworth, 1 Nov. 1835. He was educated (with the idea of be- coming a Dissenting minister) at St. John's College, London, but entered a banking house as clerk, and subsequently served for several years as assistant secretary to the Society for the Encouragement of Arts, Manufactures and Commerce. On the condition of his devoting himself to literary work for the last 40 years
in the Seventh United States infantry. He was made a captain in 1812 and in the 1812 gained distinction in defeating attack on Fort Harrison, for which he was brevetted a major. In May received a regular commission as left the service at the close of the time. Having returned to the army in 1816 and in 1819 voted to a lieutenant-colonelcy. For few years he was stationed at different posts but in 1832 during the Black War, as colonel, received the surrender of the Seminole. In 1832 he was ordered to the Seminole campaign and to the Okeechobee (25 Dec. 1837) won victory over the Indians, for which he received a brigadier-general. Taylor next four years in Florida and was a command of the First Department ny with headquarters at Fort Jessup. 8 May 1845. Taylor, in command of the Southwest, was ordered toelf in readiness to defend Texas from invasion should the latter State ac- cepts of annexation. On 30 July 1845 ordered to occupy, protect and des-and to approach the Rio Grande s of Texas and Mexico but not to enter both countries (Texas and Mexico). At the time he was cautioned to keep the Mexican settlements and posts.

Taylor selected a position at Corpus Christi on the Nueces. He then followed a series of orders from the War Department to check any Mexican endeavor to cross the Rio Grande and to do so. Taylor reported there was no concentration of Mexicans on the Rio Grande or any signs of war, but, beginning to understand the administration's intention, asked for definite orders to discontinue the War Department refused to do so for a few months a delay ensued between the Mexican government. At last, instructions from Washington, 1846. Taylor began his advance up Christi to the Rio Grande. On e arrived opposite the Mexican and began the construction of a fort, afterward called Fort Brown, upon the site of Brownsville. Taylor blocked the Rio Grande with a view of all supplies from Matamoras and many Mexican troops stationed there withdraw or to assume the offensive. General Ampudia summoned him beyond the Nueces, and with Taylor's do so the first conflict occurred on 23d our territory and shed America in the American soil. The President sent the boundary of the United States, Mexican回复 oe the American and Mexican replies.

On 2 May 1842, Taylor occupied Matamoras (18 May). With the refusal of Mexico to negotiate, Polk determined to conquer the northern provinces and in August, Taylor resumed his advance and after a three days battle captured the city of Monterey (21–23 September). By this time Polk began to distrust Taylor on account of his supposed Whig affiliations. It was em- nursing for a Democratic administration to have a Whig general reaping all the glory, and with a view toward checking his operations Polk detached most of Taylor's experienced troops for the intended advance upon Vera Cruz under Gen. Winfield Scott. Santa Anna, the Mexican commander-in-chief, learning of Taylor's weakened condition rapidly concentrated 20,000 men and marched northward to crush him. To retire to the Rio Grande meant a loss of all the prestige so far gained and, therefore, Taylor decided to fight. He took a position at the hacienda Buena Vista, five miles south of Saltillo. Here after three unsuccessful attempts by Santa Anna, Taylor gained the most decisive victory of the war and remained in undisputed possession of the region. Taylor's brilliant victory, handicapped as he had been by the authorities in Washington, suggested him as a possible Presidential candidate to the Whig politicians. Thurlow Weed learned from the general's brother, Polk, that Taylor had always been an admiring of Clark and preferred home-made goods to foreign importations. Taylor meetings became the fashion throughout the country, he was nominated at public assemblies in Ohio, Kentucky, Virginia, Pennsylvania and elsewhere, and although he had never even voted and had no views on political topics, supported by Weed, Crittenden and Stephens, he gained the nomination at the Whig Convention (May 1848) over the claims of Webster and Clay. In the succeeding campaign Taylor carried eight slave States while his opponent secured seven. The one all-absorbing question after the inauguration of Taylor was the question of what should be done with slavery in the Territories. Both parties in the campaign had side-stepped the issue, the Whigs having adopted no platform and the Democrats having trusted to the well-known views of their candidate, Lewis Cass. President Taylor, although master of a plantation in Louisiana, admitted anti-slavery leaders in the Whig party to his counsel and William H. Seward became his confidential adviser. The Wilmot proviso, the question of the organization of the Territory of Oregon and the admission of California already had demanded immediate attention. Accordingly the first message of the President was awaited with interest. Taylor already had made up his mind to recommend the admission of California as a free State and his fatherly manner breathed with devotion to the Union. But Clay and Webster determined to take matters into their own hands and in January Clay offered his plan of compromising the sectional issue. Taylor characterized the Territorial portion of Clay's measures as the "Omnibus Bill" and was preparing to oppose them when he died on 9 July 1850.

Bibliography.—Stoddard, W. O. "Zachary Taylor"; Howard, O. O. "Zachary Taylor" (in: 'Great Commanders Series of 1927').

R. C. McGARREY.
TAYLOR, Pa., town in Lackawanna County, on the Central Railroad of New Jersey and the Delaware and Lackawanna Railroad. It is situated three miles southwest of Scranton, its chief industries being coal-mining and oil mills. Pop. in 1900 was 4,215 and in 1910, 11,591.

TAYLOR, Tex., town in Williamson County, on the Missouri, Kansas and Texas and the International and Great Northern railroads, about 30 miles northeast of Austin, the capital of the State. It is in an agricultural and stockraising region. The chief manufacturing establishments are cottonseed-oil mills, cotton-compresses, railroad shops, flour and planing mills. There are about 75 manufactories, with an annual output of over $500,000. There are good banking facilities and newspapers. There are large shipments of grain, vegetables, cotton products, fruit and livestock. Pop. 5,314.

TAYLOR INSTITUTION, Oxford England, connected with the university, is designed mainly for the promotion of the study of medieval and modern technology. It owes its foundation to a bequest of Sir Robert Taylor. The building belonging to it was erected in 1848. The institution comprises four teacherships of modern European languages and a library, and there are in connection with it a school of art and an exhibition. It is under the management of nine curators, all of whom must be members of convocation. The library is open free to all members of the university, and other literary persons may be admitted by permission. The curators of the institution have also the administration of a fund bequeathed by William Thomas Horner for the encouragement of the study of the Polish and other Slavonic languages.

TAYLOR UNIVERSITY, located at Upland, Ind. The forerunner of the university was the Fort Wayne Female College, organized in 1846 at Fort Wayne, Ind. In 1852 this college united with the Collegiate Institution at the same place, and became a coeducational school. The name was changed to Taylor College in 1860. In 1893 a new charter was obtained, and the university moved to its present site, the citizens of Upland donating 10 acres of ground and $10,000. It is under the control of the National Association of Local Preachers of the Methodist Episcopal Church. It was named for Bishop Taylor, the first Methodist missionary bishop to Africa who had a part in its organization. The departments of the university are the college of liberal arts, the academy, commissioned by the State as a high school, the Red Bridge theological seminary, the school of music, the school of expression, the normal department and the commercial department. The college offers two courses, classical and scientific, leading respectively to the degrees of A.B. and B.S. A part of the work of each course is elective. The theological school offers two courses; the English Bible and the seminary course, leading to the degree of B.D. A very strong school of music accredited by the State Teachers' Association has a separate building. The course in expression requires four years. The commercial department offers two courses: bookkeeping and typistry. The spirit of the college is religious, a number of graduates have become missionaries; and the studious organizations are strong. The library contains 7,000 volumes. The students annually 340 and the faculty 19.

TAYLORVILLE, Ill., city, county of Christian County, on the South Fork Sangamon River, and on the Wabash and Baltimore and Ohio Southwestern; about 24 miles southeast of Springfield; miles southwest of Decatur. It is in a cultural and coal-mining region, and considerable manufacturing interests. There is a foundry, paper mill and manufactured wagons, agricultural implements, cistern and tile. The chief shipments are hay, livestock and manufactures. The eight churches, a high school, graded and a public library. There are three one national with a capital of $80,000, private banks. Pop. about 5,446.

TAYRA, ti-ra, a brown, elongated, like fur-bearers from the American north and South America, which sometimes large bands. It has a long bushy tail.

TAYTAY, ti-tay, Philippines, (1) a province of Paragua, island of Palawan, the northwest coast on Taytay Bay. It has one town of the province and is protected by a fort mounting several guns and capable of accommodating a garrison of 700. Agriculture and fishing are the chief industries. (estimated) 7,420. (2) Pueblo, prov. Rizal, Luzon, 10 miles east of Manila.

TAYUG, ti-yug, Philippines, province of Pangasinan, Luzon, in the extreme northwest of the province, near the Agno 34 miles east of Lingayen. It is on the way from San Quintin to Asefanan.

TCHAD, chad, or CHAD, Africa, lake in the Sudan, situated at the junction of Kamerun and the French Sahara, lat. 13° N., long. 14° E., about 750 feet above sea-level. Its area in the rainy season is about 30,000 square miles, but in the dry season it shrinks to 7,000 square miles, and is then a vast marsh, while the remaining water is shallow. The water is drinkable, although lake has no apparent outlet; it appears gradually draining up and liable eventually to a desert. Rarely is more than 20 feet of water to be encountered, and the marsh increase in size.

TCHAIKOVSKY, ch Kay'夫, the greatest of Russian composers, Voronezh government of Viatka, 7 May 1840; d. Saint Petersburg, 1893, of cholera. His father, a mining engineer, had no intention of making a musician, but had him educated at the Technological Institute in Saint Petersburg, after leaving he obtained a post in the Ministry of Education. In 1861 he wrote to his sister: 'Tell my old teacher and music critic that I am writing the theory of music with conscientious attention.' He became a professor at the Imperial Academy of Music in 1867, and later was appointed director of the St. Petersburg Conservatory.
It is generally agreed that with my in talents (I hope you will not take mere boasting) it would be a pity not your luck in this career. Shortly there- 1 entered the Conservatory, where he at the action of an Anton Rubi- no refuses that the government gives the young students to com- e and asked him to write a set of on it. He expected about a dozen, ikovskv brought him over 200! From he also took lessons in orchestra- instruments on which he practised piano and the organ; also the flute, he afterward made such admirable T'\ Nutcracker Suite' and other works. it was ere long generally appreciated; Laroche, afterward an eminent critic, to him as 'the future star of Russian his led to his being sent to Moscow in each the theory of music at the newly Conservatory. Although he disliked it, he proved a conscientious and demanding student. He had the courage to eschew the most rare time to composing; but although an almost feminine craving for ap- nd encouragement, his experiences be more than a series of disappoint- His wordly prospects were never most improved and in 1877 he married, to rise of his friends. The hasty mar- l a tragic sequel. The union was not one, and the pair soon separated. The was so despondent that he attempted to commit suicide in such a way as to avoid standing up to his chest in the icy night, in the hope of catching a cold. In the following year another influenced his life, in a happier way: not know her, and she preferred to identity concealed, but she put aside ene a sum of money which made it for him to give up his Conservatory and save his energy for his creative lany master-works now came from his had never cared for society and de- ty life, so his friends were not sur- ed, in 1885, he took a house near the Klin, where he was isolated as a character. Wagner when he 'Meistersinger' score in his villa near he became known as 'the Hermit of d refused to see any one but friends musicians as he chose now and then for a party. By constitution he was irritable and not easily fatigued; he was outdoor exercise and many of his deals came to him on his walks. He ch as he neared his 50's; his count v white and his face lined. In May visited America and gave concerts in and other cities. Two years later acted some of his works at Oxfordived the degree of doctor of music university. In the autumn of 1893 d was startled by the news of his he succumbed to an attack of cholera, short illness. There were rumors of committed suicide, but his friend rapher Kashkin disabused those. Suicide rumors were strengthened by euter of his last symphony, which is own throughout the world as the most lugubrious of all sym- phonic works. A more heart-rending wail of grief than its adagio lamento has never been heard; and as this slow movement, contrary to all precedent, closes the symphony, it seemed like an intentional farewell to the world. This music, says Huneker, is a page torn from Ecclesiastes; it is the cosmic music of the Schubert once said that the world liked best those of his songs which were born of sorrow. It was the doleful sixth symphony that made Tchaikovsky famous. Seldom has a work so great and deep won such instantaneous and success—a success so remarkable as to unduly over- shadow his other five symphonies except, to some extent, the fifth, which resembles the sixth in mood and music. Like Beethoven, Tchaikovsky is greatest in his orchestral works, which include, beside the six symphonies, seven symphonic poems: 'The Tempest'; 'Francesca da Rimini'; 'Manfred'; 'Romeo and Juliet'; 'Hamlet'; 'Fatum'; 'Le Voyevode.' In these, which contain some of his best and most mature music, he manifes his devotion to the art of Liszt and program modern music. Among his other orchestral works the three that have become most famous are the '1812' overture, the 'Marche Slave' and the 'Nutcracker Suite,' which contains the best musical numbers of one of his three ballets. His 11 operas are much less modern in spirit and structure than his symphonic works and the only one of them that has attracted much attention outside of Russia is the fourth, 'Eugene Onegin.' It has been said of his operas that 'just as the gracious beauty of Italian melody seemed doomed to pass away under a new dispensation, it was reincarnated in the works of this northern composer.' There is much beautiful melody also in some of his 100 lyrical songs; the best known of them are the 'Spanish Serenade,' 'None but a Lonely Heart,' 'Why so Pale are the Roses.' Not a few of the songs are pot- boilers and the same is true of many of his piano-forte pieces, the best of which, however, deserve to be better known. Pianists neglect them because of their awkward technique. Three piano-forte concertos, a violin concerto, a string sextet and other pieces of chamber music must be added to his positions. His work as a whole is characterized by a remarkable variety; now it is classical, even old-fashioned, now ultra-modern; now Russian, now cosmopolitan. German critics have described his symphonies as rough, patchy, barbarous, nihilistic; but music lovers the world over are showing a keener insight and are learning to love this Russian music as they learned to love the Polish music of Chopin, the Hungarian of Liszt, the Norwegian of Greig. The authoritative life of Tchaikovsky has been written by his brother Modest. A shorter volume (in English) by Rosa New- march, includes extracts from his critical writings and diaries. Consult also Kashkin, 'Reminiscences'; Huneker, 'Mezzofanti in Modern Music'; Riemann, 'Geschichte der Musik seit Beethoven.' A 'Catalogue Them- atique' of the compositions is issued by Jur- genson, Moscow.

TE DEUM LAUDAMUS, té dé'-úm lá'-dá'-mús, or more abbreviated, TE DEUM, is the beginning of the hymn of praise usually ascribed to Saint Ambrose and Saint Augustine, although it cannot be traced as far back as the end of the 5th century, while Saint Augustine died in 430. The opening words, meaning, "We praise thee as God," show that it was originally a hymn to Christ, but it is now always regarded as a hymn to the Father, the English version beginning, "We praise thee, O God." In addition to its place in church services it is often sung on particular occasions, as on the news of victories and on high festival days. Among the great composers of music for this hymn are Hasse, Naumann, Haydn and Handel.

TEA, an evergreen shrub or small tree (Camellia thea) of the order (Theaceae). The plant naturally attains a height of 30 feet, but under cultivation is pruned so that it rarely exceeds 12 inches in height. It bears alternate leaves, about four inches long and rather large fragrant white flowers singly or in twos or threes, mostly in the axils of the leaves. It is a native of India and China, and has been cultivated in the latter country more than 2,000 years. Of several recognized species, only two have become commercially valuable: C. thea, var. Bohea, and C. thea, var. viridis. The latter is indigenous to India, the former recognized as a hybrid of Chinese species, probably with the original India variety.

Cultivation. - The ground on which a plantation of tea is to be set out is dug over in trenches to the depth of at least 18 inches, and 24 inches is preferred if the expense — about double — is not deterrent. As the plantation is of a permanent character, intended for a productive period of probably 30 years, every effort is made to have the soil in the best condition, and well manured. The plants are taken from a nursery where they have been grown from seed for six to 12 months, and set four feet apart both ways for "hill" culture. Where the ground is especially favorable they are set five feet apart. On poor soil the "hedge" system is practised, the plants being planted 18 inches apart in the hedge, and the hedges five feet apart. The plant has a tap-root descending eight to 10 feet into the earth. From this the feeding roots ramify in all directions. The cultivation consists in keeping the ground loose and free from weeds by surface hoeing, and once a year trenching the soil — from 18 inches in depth between the rows to nine inches next the "collar" of the plants. This is done in the late autumn, just after pruning, and the pruning along with green manure, preferably from leguminous plants, are spread under. These prunings are estimated to restore to the soil: 95 pounds of combined nitrogen, 56 pounds of phosphates and 190 pounds of phosphoric acid per acre. The pruning is done while the plant is passive, usually in December. On the hill plantations pruning is done annually, on level gardens, every other year or every third year; the practice being to prune alternate one-half or one-third of the plantation. The unpruned trees furnish the smaller leaves and, therefore, the higher grade tea, and flushes come earlier, thus extending the season. On new plantations pruning when the trees are 12 to 18 months old, at time the centre stem is cut down to the branch, or even six inches above the ground, the object being to produce a growth of branches and shoots of leaves which may be plucked without in the plant. The second pruning takes off a thing to a level of 18 inches above the ground. As much of the tea is picked by children the yield is about 150 pounds per acre. The yield of about 400 pounds per acre begins the fifth year. The plant continues to grow well until its 10th year, when it is cut and new sprouts developed from the bud-stems removed at the first picking. The plantations are pruned about 30 times during the season, with the obtaining the leaves while they are in the best condition. The bud produces the quality of tea; the partly open buds being slightly less valuable. The next leaves below distinctly coarser than the bud leaves. It is inadvisable to pluck the bud and the first leaves. Many growers, however, do not pluck the bud and the first three leaves. The first few crops are thus very large, but the remainder of the season are relatively small. The quality, however, does not wholly depend upon the plucking, but depends upon the soil and the climate. The average weight of two and one-half ounces of fine tea per plant per season.

Processing. - The leaves after plucking is determined by the number of leaves of tea to be produced. In black tea the leaves are wilted or on trays in a draft of cool air orduced by fans. This is continued until the leaves are soft and flaccid. The average time for withering is 18 hours. Less time is required if not sufficient development of the enzyme required for the subsequent fermentation upon which the flavor of the tea so largely depends. Withering is followed by rolling on tables of granite, the motion of the leaves being to crush the cells of the leaf and break its structure. In this process the leaves are rolled, pressing the leaves incidentally receive the active twist necessary in finished tea.
upied in rolling is from 20 to 40 min-

other form of brick tea is made into tablet
form, four and one-half inches square and one-
and one-fourth inches thick and weighing half
a pound each.

Tea Culture in the United States.—In the
United States the first tea shrub was planted at
Middleton Barony, S. C., in 1800 by the French
botanist Micheaux. It was still living at the
close of the 19th century, when it was about 15
feet high. In 1848 experiments were made upon
an extensive scale by Junius Smith of Green-
ville, S. C., and in 1858 the government engaged
Robert Fortune to collect tea seed for distri-
bution in the South. These experiments were cut
short, the former by the death of the experi-
menter, the latter by the Civil War. About
1880, the United States Department of Agri-
culture commenced experiments which were
abandoned owing to the want of a
chness, a short distance and the
nizing headquarters.
About 10 years later Dr. Charles U.
Shepard of Summerville, S. C., devoted his
private means to tea experimentation. His opin-
ion was that the previous experiments had not
been conclusive and that the production of high
grade teas at a profit to the grower could be
accomplished in many Southern States and that
a demonstration would attract capital to the
industry. Once demonstrated as profitable he be-
lieved that the industry would furnish employ-
ment to many thousands of people, especially
women and children, and would make valuable
large areas of land which yielded little or noth-
ing. In 1900 he had about 60 acres planted to
this crop, a factory fully equipped, a trained
band of pickers and facilities for meeting every
require of planting to final sale. In 1900
the yield was about 5,000 pounds and when the
present area reaches full bearing the annual
output should be more than 12,000 pounds.

The tea plant, though a native of a sub-
tropical climate, will succeed at high elevations
in tropical countries and some of the numerous
varieties will even withstand frost. In South
Carolina the plants have resisted a temperature
of zero, but the yield was lessened about 50 per
cent. In 1902, after two years, this is the lowest recorded tem-
perature in that locality during 150 years.
Ample water, especially during the leaf-forming
season, is essential. This is supplied in the
East by copious rains, but in the United States,
where the rainfall is less than one-half the
Eastern annual average, the deficiency is made
up by improved methods of tillage or by arti-
ficial irrigation or both. In the East the tea
gardens are generally planted on high ground
or slopes so as to permit the excess water to
seep away; in America they are planted on
rather low ground such as well-drained pond-
beds and swamps. Such lands are also natu-
ral rich as a rule and, therefore, demand less
initial application of fertilizers.

History.—The history of the tea-growing
industry is said to have commenced in Korea
before the 4th century before Christ, and to
have reached Japan more than 1,000 years later.
Tea was unknown to Europeans until the 16th
century when Maffel, a Portuguese, mentions
it in his "Historia Indicis" as a product of
Japan and China. Not until 1615, however, was
it mentioned by an Englishman, when Wickman wrote about it in a letter now owned by the East India Company. During that century small quantities found their way as presents to wealthy Londoners or later into the markets where they could command £1 to £5 a pound. In 1657 a considerable quantity was purchased by Thomas Garraway, who opened a sort of restaurant where the beverage was served. As the importations increased, the customs and the excise each affixed duties. At one time (1660–89) a duty of 8d. a gallon was levied upon the beverage. And somewhat later 5s. plus an ad valorem duty of 5 per cent was also operative. The American tea trade began in 1784 and within three years had developed to more than 1,000,000 pounds. The first direct importation from Japan came from Yokohama to San Francisco in 1868. Since 1870 the annual average importation is somewhat in excess of $15,000,000.

From the beginning of the commerce in tea, China has held first place as a producing and exporting country. The choicest grades, however, are probably unknown in America, but are consumed mostly at home or in Russia, where they command enormous prices. The reasons assigned for the non-exportation to distant countries are that the quality usually deteriorates during long transportation, and that some kinds do not keep well unless highly *fired,* a process which impairs their flavor. The industry attracted the attention of the English in India and in 1836 Royle and Faloono, British botanists, commenced in Ceylon to experiment upon an extensive scale. The result was several brands of tea which were superior to many of the Chinese teas. Ceylon began to market tea in 1873 and the industry there has continued to thrive. Tea has been grown more or less in other sub-tropical and tropical climates, notably in South Africa, where somewhat more than a domestic supply is raised.

The large number of plants whose leaves have been used as substitutes for tea may be grouped as resembling or not resembling the real plant in composition. The best known of the former are as follows: Maté, Paraguay tea, Jesuit’s or Saint Bartholomew’s tea, which is obtained from the leaves of a South American species of holly (*Ilex paraguariensis*). This is extensively used in various South American countries, especially in the Argentine Republic, where the annual consumption is estimated at 13,000 pounds per capita, or about 29,000,000 pounds. Kola nut, coffee leaves and guarana are also used, but to a smaller extent. The principal substitutes unlike tea are probably Siberian tea (*Narcissus crassifolius*), Chilean tea (*Eugenia ungii*), Appalachian tea (*Prinos glabrata*), Labrador tea (*Ledum balsamii*), and New Jersey tea (*Ceanothus americanus*). The last was used during the War of Independence and also during the War of the Rebellion. It is described as a good substitute for indifferent black tea. The leaves of the partridge berry (*Mitchella repens*) are sometimes used in America.

In conservatories and greenhouses tea is often grown as ornamental plants and as ornamental shrubs. The tea geranium, a hybrid like their close relatives, the camellias, but are less popular because more limited in their uses, especially because their flowers are auxiliary and hence less useful for cutting than those of the camellias.

**Production.**—The world’s annual production of tea, a pound, amounted to something over 800,000,000 pounds. The World War severely affected production and shipment of the crop that it is necessary to take the figures of production for 1912, as being the latest complete record under normal conditions, to form an accurate idea of the tea-growing industry. In that year the area devoted to tea were as follows: China, 5,120,000 acres (approximately); India, 575,000 acres, of which 354,276 acres were in Assam; Ceylon, about 359,000 acres; Java, nearly 100,000 acres; Japan, about 100,000 acres; South Africa (Natal and Nyasassland) about 6,400 acres. The crops sold in the world’s markets from these producing countries amounted to a grand total of 731,000,000 pounds, contributed thus: 1

- China, 112,000,000 pounds;
- Ceylon, 193,000,000 pounds;
- Java, 65,000,000 pounds;
- Japan, 43,000,000 pounds;
- Formosa, 25,000,000 pounds.

**Consumption.**—The chief purchasing countries of the 1912 crop were: United Kingdom, 295,000,000 pounds; Russia, 147,000,000 pounds; United States, 83,000,000 pounds; Canada, 34,000,000 pounds; Australia, 29,000,000 pounds; Holland, 12,000,000 pounds; Germany, 9,000,000 pounds; New Zealand, 7,000,000 pounds; South Africa, 7,000,000 pounds. In per capita consumption the British Empire as a whole was remarkable in degree the largest consumer, the average being 6.2 pounds, about 10 times the per capita consumption of all the rest of the world put together (excluding the United States). For the individual countries the per capita consumption figures were:

- New Zealand, 7.4 pounds;
- Australia, 6.8 pounds;
- United Kingdom, 6.4 pounds;
- Canada, 4.3 pounds; Holland, 2.1 pounds;
- South Africa, 1.2 pounds;
- United States, 0.9 pound; Russia, 0.8 pound; Germany, 0.1 pound; France, 0.07 pound.

**Infusion.**—As found in the market tea yields from 31 to 49 per cent of its substance in an infusion with boiling water, the Indian tea giving slightly more than the Ceylon teas, and the China teas slightly less. In this water extract the tannin constituent ranges from 14.3 per cent in India teas and 12.29 per cent in Ceylon teas to 9.50 per cent in China teas. (With thorough fermentation the proportion of tannin would fall below 5 per cent.) Caffeine varies from 2.78 to 3.84 per cent in India teas, and ranges up to 4.14 per cent in Ceylon tea and 4.91 per cent in tea dust. In making the infusion for beverage purposes the finest flavored tea is produced by pouring freshly and actively boiling water upon the dry leaves and allowing it to stand not longer than one and one-half minutes, when the infusion should be immediately poured off the grounds. This brief infusion is sufficiently long to absorb practically all of the delicate essential oil which gives the tea its particular flavor. It is also long enough to dissolve out sufficient of the tannic acid to make the taste sprightly, without being astrigent. The infusion will also contain about four-fifths of the contained caffeine. The strong, high quality preferred by tea drinkers is gained by a five-minute infusion.
TEA, VARIETIES OF—TEACH

TEA-NOTE. The importation of tea into the United States for the fiscal year ended 30 June, 1898, reached the record figure of £1,314,933, despite the great difficulties of a scarce and expensive ocean tonnage. The value of the tea was $30,889,030. Of the whole, 4 pounds came from China; 44,546,467 from India and Ceylon, and 21,082,866 from Japan.

H., 'Tea' (New York 1803); H., 'Les Cultures Coloniales' (Paris 1810s); B penters' Association, 'Tea in Ceylon' (Ceylon 1910); 'Tea and Coffee Trade' (Table of the Principal Kinds of Teas) (New York 1910); 'The Manufacture of Tea in the United States' (Washington 1912).

M. G. KAINS, Crop Expert.

Varieties of Tea. Teas were named after the place of origin, as tea-uuing all from that country, but more often a brownish-green leaf tea, well-picked. The qualities are indicated as long or well-curled, light-colored, etc. Tea is named mostly after the large trees; the varieties are termed pekoe souchongs, souchong, congou, leaf, etc.; the congou is black, the black inclining to red, the pekoe yellowish tips, while the red leaf is souchong. The hyson is a large-leaved tea; the hyson skin is the remnants of the leaves put in up hyson. Oolong is a yellow tea, and Twankay a green tea imperfectly rolled. Bohea is a standa peak tea, gathered three times a year from the variety largely advertised as breakfast is souchong, while imperial oolong is a long, yellow leaf, tight, Imperial teas are named in the trade as leaf, dust, ends, fannings, etc.

IN AMERICA. About 1880 the tea-a Department of Agriculture established a tea-growing plantation near Sum Cherry. S. C., and various varieties were an experimental way. Later the plan and the Pinhe Tea Gardens 1 the suburbs, being supplied with water from a tract of about 100 acres and tured and cured by competent people. experiments were made at a place of tea, in Colleton County, S. C., and Texas. the captain, Robert Maynard, slew Thatch in a hand-to-hand struggle. His career is one of the most romantic in the history of American piracy. "Blackbeard the Pirate" being considered the ideal type of the pirate of fiction. Consult his "Life" in Charles Johnson's "Lives of the Pirates." (1724).

TEACHERS, Professional Training of. Richard Muleaster of London advocated the professional training of teachers as early as 1561 and suggested that a teachers' college be organized as a department in a university. Nothing definite or permanent appears to have come from this suggestion. The first genuine effort for the professional training of teachers undertaken in the world was undoubtedly by Jean-Baptiste de La Salle at Rheims in 1681.

Three years later the institution which he founded at Rheims became known as the "Institute of the Brothers of the Christian Schools." He later established a similar school at Paris. In this school he organized a regular, systematic course of instruction for the preparation of teachers in the profession. In 1697 he selected certain poor students in attendance upon this school and organized them into a "teachers' class." The members of this class gave instruction to the other pupils in the orphans' school, and for this service Francke allowed them free tuition and board. Twelve years later Francke selected 12 students from the pupils in his orphan asylum to be trained as teachers. These students were devoted to "the study of the "their piety, knowledge, and aptness to teach." Francke called this institution a "Teachers' Seminary." Hecker -- a pupil of Francke -- has the honor of establishing the first regularly organized institution devoted to the special work of training teachers. This school was established at Pomerania, Prussia, in 1735, and Hecker gave to it the name used by Francke and called it a teachers' seminary. Hecker established a second school of this type at Berlin in 1748. Frederick the Great gave official endorsement to the effort to provide special training for those who were to be employed as teachers in the schools, by raising Hecker's school to the rank of a royal primary school for the purpose of training parish clerks and teachers. He gave this school further royal favor by directing that all parish clerks and all teachers appointed by the Crown should be selected from its students. Little progress was made in the establishment of institutions of this kind or in the training of teachers in Europe until after the French Revolution. At the beginning of the 19th century, the development of institutions to train teachers took on new life and the Prussian system of normal schools was firmly established. Six normal schools had been organized in that country.

It was about this time that the subject of preparing teachers for public schools began to receive attention in America. Men interested in educational reform began to consider this subject. The manner in which these men first approached the subject is not indicated that they were familiar with what had been done in Europe; a training of teachers or the establishment of normal schools was practically unknown.

The paper prepared by these men revealed a consciousness of the necessity of establishing adequate educational facilities in America and of preparing teachers to take charge of such schools as should be established. The papers written by these men indicate that these writers were speaking from the experiences and needs of the nation and not from historical knowledge of what had taken place in other countries. Among the numerous articles which appeared at this time and which exerted great influence in developing the idea that teachers should be professionally trained were the address of Denison Olmstead in 1810 on the "State of Education in Connecticut," the pamphlet issued in 1823 by William Russell, principal of the New Haven Academy, on the subject of "Suggestions on Education," the publication entitled "Lectures on School-keeping" issued in 1829 by Samuel R. Hall who founded a school for training teachers at Concord, Vt., in 1823, the articles published by James G. Carter in the Boston Patriot in the winter of 1824-25, the paper of Rev. Thomas H. Gallaudet in 1825, the pamphlet for the Education of the Instructors of Youth," the pamphlet of Walter R. Johnson of Germantown, Pa., issued in 1825, on "Observations of the Improvement of Seminaries of Learning in the United States, with suggestions for its Accomplishment," and many others. These articles gave to the public much valuable literature on the subject of education in general as well as upon the importance of special training for those who were to teach. The democracy of the nation was demanding and with this development came a demand for schools.

In the beginning of the 19th century 15 States either established systems of schools or reorganized existing systems. New York provided for State supervision of her schools in 1812 and 11 other States soon followed in making similar provision. The expansion, enlargement and improvement of educational facilities has always been coupled with a demand for better teachers.

The type of teachers employed in the schools in many cases was a potential product of a system of training teachers. The men employed as teachers in the academies and colleges were generally men of education and character. This was not true of the men employed in the primary schools. The primary school teachers possessed little education, had received, of course, no training and had no intention of remaining permanently in the teaching service. Men often sent their sons to Europe to be educated and sometimes imported teachers from Europe to instruct their sons. Many were unable to get other employment because of their lack of education or of proper character and often enlisted in the teaching ranks. But even in this demoralized situation, able young men who were either working their way through college or had completed their college courses and intended to enter either the professions of the law, medicine, or ministry, or business careers, taught a few terms or years. Among the many men who have long been known for their work in this field, many may be mentioned: John Adams, Eli Whitney, Daniel Webster, William Ellery Channing, William H. Seward, Salmon P. Chase, and, in later years, James G. Blaine and Elihu Root. As late as 1887 Horace Mann stated that, of the teachers employed in the State of Massachus-
side of the city of Boston, about 200 to devote themselves to teaching and others were not generally qualified and to show the year in which the they get to the end of the term than they were to give during the term.

men in public affairs in all parts of the city recognized this condition in educators and gave it consideration. The New City 1845, the teachers of New York City in an organization known as the "Society of Teachers." The purpose of this society was to promote the interests of its members generally. Members were the society by ballot, and a three-to-one vote was necessary to an election. The society did much of the work now performed by the professional supervisory staff of the system. It passed upon the qualifications of teachers, upon textbooks, upon the professional decorum of teachers and the pedagogical questions of that society.

It had been a voluntary organization until 1839 when it was incorporated by Act of the New York Legislature. The petition for incorporation carried in the New York City. The petition and the original society of 1794 were merged into the charter granted the organization in the following language, the objects of which are:

1. Relief and benefit of decayed teachers and their widows and children of deceased teachers, and for this purpose subjects and for the promotion of the interests of the members of the society.

The society immediately entered upon a for the intellectual improvement of its members and its official reports show that this work was carried on with great success for several years. The society gave special work to train and equip teachers to teach in New York. This society was undoubtedly the most successful institution of its kind in America which gave definite training to teachers for public schools.

Through the initiative and influence of Clarkin, the legislator of New York, a new organization was created called the "Society for establishing a school in the city of New York for the support of poor children as do not receive the benefit of the teaching services of the city schools." This society became known as the School Society of New York. It reported for 1814 contains the following:

the commencement of the society it has been the great interest to train up young men for the teachers in similar institutions. The realization of this is in part accomplished.

It is stated in his work on DeWitt that a youth educated in this school would become a teacher in a similar school in Norwich, N. Y., and that the society had an application from Newburgh, N. Y., her. The Free School Society adopted the master system of schools. The report of 1818 states that the society was doing a great deal of work, and specifically states that the teachers were not only provided for, but were also given specific directions as to what the society was doing to aid teachers and specifically states that those in the schools where they were properly trained.

The first organization endeavoring to train teachers for public schools. See article Lancaster Schools, Vol. 16, p. 687.

The official records do not indicate the precise year in which the school was founded. The school was founded in 1821, and the 1821 report contains the announcement that the societies were training teachers for the academies in New York State. The report of the Regents for 1821 contains the statement that the academies were training teachers for the common schools and the Regents expressed the opinion that the schools of the State must look to the academies for their supply of teachers. In the annual report of the Regents for 1823 the statement is made that because of the distribution of public funds under its direction to the academies subject to its supervision, such action "insures a supply of competent teachers for the common schools." New York was undoubtedly the first State which took specific action to solve the problem of providing trained teachers for the common schools. One of the vital questions in the establishment of agencies for the training of teachers was the manner in which the funds were to be raised in New York. This question was, Shall the state establish educational institutions to be utilized for this purpose or shall separate institutions devoted to such work be organized? The academies in New York were numerous, influential and under the control of the Regents. The friends of these institutions were zealous in their efforts to have the academies designated to train teachers. The State was giving their institutions financial support from the literature fund. The academies began to give special training to those who were going out to teach as early as 1821, and such instruction has been given continuously since that date. The friends of the academies endeavored to increase the amount of State aid to these institutions and based their argument upon the service which the academies were rendering the State in training teachers. They were successful in 1827 and not only succeeded in obtaining larger financial support but also obtained statutory recognition to train teachers without specifying how such service should be performed. The Regents, however, at once designated certain academies for this purpose and other academies continued to do such work voluntarily. The academies still pressed their interests at the legislature and in 1834 obtained the enactment of a law specifically authorizing the Regents to designate academies in which training classes should be organized. These training classes have been continued since that time and 80 were maintained in the year 1918-19. Through this agency about 25,000 teachers have been supplied to the rural schools of the State.

In 1823 Rev. Samuel Hall opened a school at Concord, Vt., for the training of teachers. He was sent to this town as a preacher by the Domestic Missionary Society of Vermont. He was asked to remain upon the distinct understanding that he should have no connection with any school for the training of teachers. He admitted to his school a class of young pupils for the purpose of having the opportunity of showing them the best methods of teaching and governing a school. The literature relative to this school shows that Mr. Hall had no
textbooks, periodical or other helps or equipment, and that he conducted the school on his own knowledge and judgment of educational methods on the basis of his experience in teaching. Growing out of his experience in this school he gave a series of lectures on 'school keeping.' There was a great demand for this work and the supply was soon exhausted. The State of New York purchased 10,000 copies of a revised issue. This was the first time this sort of help was afforded for such work in existing institutions. He had won a victory in the State of New York, the question was not permanently settled. The training of teachers was being considered in a broad, comprehensive manner by thoughtful educators, by State supervisory school officers, by the superintendents of schools, and in 1825 a strong presentation of the subject by Walter R. Johnson of Germantown, Pa., published in 1825 and of Rev. Thomas H. Gallaudet in the same year made a deep impression upon the public mind. He delivered a paper in the solution of the problem. Dr. Philip Lindsley in his inaugural address as president of Cumberland College, Nashville, Tenn., in 1825, stated that the teacher needed training for his work as much as a lawyer or doctor and urged the establishment of teachers' seminaries and in 1830 he appeared before the legislature of that State and advocated the establishment of such seminaries. In the same year Gov. DeWitt Clinton in his message to the legislature of New York also advocated the establishment of a seminary for teachers. In 1836 State Superintendent Spencer in a special report to the senate of New York also urged the plan of teachers' seminaries. Governor Lincoln of Massachusetts in his messages of 1826 and 1827 to the legislature of that State urged the importance of making provision for the training of teachers. The American Institute of Instruction petitioned the legislature of Massachusetts upon the same subject in 1827. Dr. George J. Barlow in a committee report of 1834-35, Chauncey Colton, president of Bristol College, in 1833 urged upon the legislature of Pennsylvania the establishment of courses in colleges for the training of teachers and that the common schools in the town should be used as practice departments. In December 1829, 37 citizens of Rochester, N. Y., called a public meeting in that city to consider the educational needs of the times. This committee prepared a report which was adopted by the meeting and among the recommendations was one for a State seminary to train teachers. A comprehensive plan was proposed for the administration of the seminary and for the course of study. This plan proposed "a farm of 100 to 200 acres, under the direction of an intelligent farmer, a nursery and a nurseryman and a mechanics shop with a general assortment of tools, such as the miscellaneous business of the farm and garden may require." In 1836, a public meeting of citizens in Philadelphia recommended the establishment of a teachers' seminary as an independent institution containing a three years' course of study and a model school. In the State Superintendent Burrowes of Pennsylvania recommended an appropriation of $5,000 for the establishment of a model school in the eastern part of the State and in the western part, for the training of teachers. In 1829 the 'Annals of Education' by Woodbridge published a translation of German periodicals giving an account of Prussian semi-naries for the training of teachers. Articles on and translations of C. Report on Public Instruction in Germany appeared between 1830 and 1835. These were published extensively in the newspapers of the country. It was out of all discussions and proposals that the school idea developed in America. Then two men in Massachusetts who rendered service in the successful effort to establ normal school. These men were Mr. C. Brooks and Mr. Freeman. Mr. Brooks made a careful study of the Prussian system of normal schools and in a Thanksgiving speech in 1835 at Hingham he explained that he prepared three lectures on the subject and he delivered them in a series of articles. He issued a circular inviting citizens of Ply mouth County to meet him to consider the subject. This invitation included every board of education of the county. A large audience met him at the courthouse. The address impressed Ichabod Morton that he offered to contribute $1,000 for the establishment of a normal school at Plymouth. Mr. Brooks traveled 2,000 miles, delivering addresses in the county and contributed a continuous series of articles on the subject to the newspapers. A number of representatives invited him to address them. He also addressed the legislature of Vermont, New Hampshire, Maine and New Jersey, and many cities and villages in States. Mr. Carter, who has often been the 'Father of Normal Schools,' had a comprehensive outline of his plan for the training of teachers in the articles which he wrote for the Boston Patriotic and other papers. He emphasized the essential elements in the work of a normal school. These were: (1) the development of sound scholarship; (2) a course of study in the science and art of education; (3) practical school. Nearly all the schools in these points are the vital features of normal schools of America. The people of the town of Lancaster, Mass., offered their very large sum of money for the establishment of a school in Lancaster. He later put obstacles in his way and the offer failed. In 1835 Mr. Carter was elected to the legislature, and in 1836 he was made a member of the committee on education. He was successful in getting the legislature to establish a seminary for the training of teachers, but failed in his efforts. He had succeeded in getting the bill providing for a State Board of Education, which became a law in 1837. He was a strong advocate of the establishment of normal schools. He obtained the assistance of the General Assembly to provide for the establishment of a seminary for the training of teachers. Edmund Dwight, a member of the legislature, was the drafter of the bill that was passed. He was a strong advocate of the establishment of normal schools.
establishment of institutions to train teachers, the State would appropriate an additional $10,000. Mr. Mann communicated this intention to the legislature 12 March 1838. On 12 March a joint committee, which had previously reported a resolution appropriating $10,000 to the State Board of Education for the training of teachers, but which was amended to increase the amount to $10,000, was given executive approval to spend $10,000 to the State Board of Education for the training of teachers, but it was subsequently reduced to $10,000. The establishment of these schools in Massachusetts and in New York did not prevent their enemies from opposing the continuation or development of such schools. Governor Dix of New York, who had been friendly to the academies for many years, was decidedly hostile to such schools in his message of 1874, and Governor Robinson, in his messages of 1877 and 1879, made a direct attack upon normal schools and stated that they were "wholly useless." In the same year the legislature authorized an investigation of such schools. In 1840 the house of representatives of Massachusetts directed the committee on education to consider the expediency of abolishing the State Board of Education and the State normal school. The majority of that committee prepared a report recommending that both should be abolished and presented a bill to carry out such recommendation. The measure failed to pass. It is in the face of such determined opposition that the plan outlined that the normal schools have arisen in America. The success of these schools in New York and of the Albany school made it possible to develop the system of normal schools now in existence in the United States. Others were gradually established. The New British school was organized in 1849, the Ypsilanti in 1852 and about 70 others prior to 1875. At the present time there are 237 public State normal schools, and before the war the number of students in attendance upon such institutions preparing to become teachers was nearly 100,000. There are also 45 private normal schools attended by nearly 6,000 pupils.

These schools are supported by State appropriations. In some States they are wholly under the supervision of the State educational authorities. In others they are only partially under such supervision and in some the State exercises practically no supervision or control over them at all. The age of admission is usually 16 years. The courses of study are generally either two years or four years, depending upon the qualifications of the students when they enter. In some schools, as those of New York, the requirements for admission are graduation from a four-years' approved high school course. In such normal schools the course is two years and is devoted to professional work. In many schools a student is admitted from the elementary schools and for such students the course is generally four years. When normal schools were first organized, their courses of study included much academic instruction. The development of high schools throughout the country has resulted in decreasing the academic work in normal schools and in increasing the professional work. The present tendency is to lengthen the courses so as to cover three or four years. In New York the Board of Regents has recently authorized three-year courses in all the normal schools of that State. In many of these schools special courses, such as kindergarten, drawing, music, manual training, home making, rural school and other courses are given. Practice departments or
model schools are maintained in all the normal schools and in many of the normal schools use the public schools for practice departments. These schools generally train teachers for the elementary schools, although some prepare teachers for secondary schools also. Some of the normal schools give extension courses on Saturday and during vacation periods and some take their students into the rural schools for practice work and for demonstration.

The State College for Teachers at Albany prepares teachers for secondary schools only. The courses cover a period of four years, and the admission requirements are the completion of a four-years' approved high school course. The work in this institution is of collegiate grade and degrees are conferred upon those who complete prescribed courses. There are 800 students in this institution preparing to teach in the high schools of the State.

The Education Law in New York has required since 1875 that all teachers employed in the city and in the villages having a population of 5,000 or more shall have graduated from a four-years' high school course and thereafter from a two-years' professional course (Chapter 1031, Laws of 1895). In most cities, and in the villages, the same requirement is prescribed. Normal schools are unable to meet the demand for teachers and many cities have organized city training or city normal schools. These schools generally maintain entrance requirements and courses of study equivalent to those of the normal schools. These schools prepare teachers for the kindergarten and the elementary schools. New York maintains three of these schools, Philadelphia, two, and a school of this type is maintained in Albany, Buffalo, Rochester, Syracuse, Schenectady, Yonkers, Boston, Pittsburgh, Cincinnati and in most of the large cities of the country.

Within the last 25 years there has been a demand in all parts of the country for better trained teachers in the rural schools. About one-third of the teachers employed in these schools have had no training whatever. This demand has resulted in the establishment of numerous types in about one-half of the States for training teachers for rural schools. In New York the training classes maintained in high schools have supplied these teachers for years. Missouri, Vermont and several other States have organized similar classes in their high schools for training rural school teachers. In Michigan, county normal training classes have been organized, but these do not differ materially from the training classes in these other States. Wisconsin has organized not only this type of training class in her high schools, but she has also organized county training schools. These county training schools are in no way connected with other schools, but are generally maintained in separate buildings and have an independent organization. The requirements for admission to these classes vary. In New York it is high school graduation. In most States it is the completion of two years' high school work. In Pennsylvania the last year of the high school course is devoted to teacher training. In other States students are admitted from the elementary schools. The course of study usually covers one year and the age of admission is from 16 to 17 years. Many of the State normal schools maintain special courses for rural teachers.

Several efforts were made to establish chairs of pedagogy or colleges of education in the universities which would take rank with the department of law, medicine or engineering. New York University established a school of the philosophy of education for educating teachers of common schools in 1832. Thomas H. Gallaudet occupied this chair from 1832 to 1834. It seems to have been abandoned at that time. Brown University established a similar course in 1850, but discontinued it in 1855. Horace Mann included as an elective study in the regular course of Antioch College, Ohio, in 1853 the theory and practice of teaching. From 1853 to 1873 Iowa University offered courses for teachers and in 1878 opened its college of normal instruction.

On the recommendation President Angell, Michigan University established in 1879 a chair of the science and art of teaching for the following purposes: To fit university students for the higher positions in the public school service; to promote educational science; to teach the history of education and of educational doctrine; to secure to teaching the rights and privileges of a profession, and to give a more perfect unity to the State educational system by bringing the secondary schools into closer relation with the university. A plan was proposed for giving instruction in the science and art of teaching in the University in 1838, but was not carried out at that time. In 1880 the college opened certain courses for training teachers and in 1888 Teachers' College was founded and in 1889 chartered. Doctor Nicholas Murray Butler, now president of Columbia University, was the first head of this new institution and as president of Columbia is now president of Teachers' College. This college is one of the notable institutions of the world. It trains teachers, superintendents, directors and superintendents for all the higher technical and professional positions in the teaching and supervisory staffs of the city and State school systems of the country. Several thousand students are annually enrolled in this institution. All of the teachers of the country now maintain departments of education or colleges which are rapidly taking rank with the departments or colleges of law, medicine and engineering and are meeting the demand for specialists which the developing public educational systems of the country require.

Summer schools have become a strong and influential factor in the training of teachers. Harvard University was one of the pioneer institutions in America to give summer courses. Harvard has given such courses for 48 years. Martha's Vineyard Summer Institute, organized at Cottage City, Mass., in 1878 by Col. Homer Sprague, has been one of the notable institutions of this type. It was closed in 1905. In 1879 the Sunday School Assembly at Chautauqua, N. Y., organized a summer course of psychology and pedagogy which soon became an important course. In 1896 the number of teachers was increased and the summer sessions were held at Chautauqua give several courses for teachers. After these and some other institutions had been successful in holding summer sessions, the work was rapidly taken up by
schools, colleges and universities, and of several important institutions at the college level. About 800 schools were held in 1919 and the attendance was approximately 300,000. Columbia University established three institutes in 1837. Mr. Stephen Sweet opened a temporary school for the training of teachers in 1842. Mr. Sweet contemplated opening a permanent school in the winter of 1843. The work which he did in the winter school is quite similar to that as later done in teachers' institutes. Schools organized by Mr. Sweet became generally as temporary schools for teachers, or temporary normal schools. Because of this, he was able to train teachers in various parts of the country which had been organized in New York.

In 1843 Dr. Henry Barnard of Connecticut was one of the early leaders in the field of education. He opened a school at Ithaca and was organized as the superintendent of schools. The fame of this institute spread throughout the country. Within three years, 2000 teachers were trained in Massachusetts, Ohio, Rhode Island, Indiana, New Hampshire and Vermont. It is clear that New York and Pennsylvania were the centers of the system of institutes organized in other States. Institutes were established in New York State in 1812, and conferences under the direction of superintendents were substituted there. These conferences were held in many States. In Arkansas and Ohio they were an important part of the teacher training process. They were managed and generally formed the resident of the supervisory district. Schools are closed for the purpose of conferences on the promotion of the arts of art in relation to school management, and other school work, and the general good of all the schools of the district. Appropriations are made in some instances by the State and in others by the county to meet expenses paid by teachers. Attendance is usually compulsory. The method of instruction is generally the lecture system. These lectures are on subject matter, school discipline, school organization, school management, methods of instruction popular and inspirational themes. In some instances they depart from the primary purposes of an institute which is to improve the teaching force and the form of community centers. In such cases they have become mass meetings instead of classrooms for instruction.

In 1895 the Paulist Fathers in New York organized an institute for the general improvement of the teachers in Catholic schools. It is called the National Catholic Teachers' Institute, and under the general management of this organization provision is made for the maintenance of local institutes in various parts of the country for the benefit of the teaching orders connected with Catholic schools.

Teachers' reading circles have exerted a strong influence in developing a professional spirit among the teaching fraternity. The first circle was probably organized in Ohio in 1832 upon the suggestion of Dr. L. L. Williams, a teacher in that State. The circle was formulated somewhat upon the plan of the Chautauqua literary course. Many of the other States of the Central West and West have organized similar circles. There are now several national and state organizations of the State Teachers' Association or the State Education Department. In some States the circle is under the joint management of such authorities. A definite course of reading is prescribed, textbooks suggested and examinations prescribed. Many States give some credit in their plan of certification to those who have done successful work in the circle. In 1915 the National Rural Teachers' Reading Circle was organized under the direction of the Bureau of Education at Washington.

TEACHERS' COLLEGE—TEACHING METHODS AND SYSTEMS

THOMAS E. FINEGAN,
Deputy Commissioner of Education and Assistant Commissioner for Elementary Education, State of New York.

TEACHERS' COLLEGE, a school for the training of teachers, affiliated with Columbia University. For several years the college has maintained courses for teachers in New York schools, and since 1897 has made these courses an integral part of the regular college courses. The continual increase in the number of teachers taking these courses led to the organization of an extension department in 1901 which includes the entire university system. The university accepts courses in education as part of the requirement for the degrees of A.B., A.M, and Ph.D. The college diploma is conferred upon students who have successfully completed some of the general courses, and a departmental diploma upon those who have fitted themselves for particular branches of school work. Undergraduate students of Columbia and Barnard colleges may obtain the diploma of Teachers' College when they receive the degree of bachelor of arts.

These are the undergraduate courses: Secondary course leading to the degree of A.B., and the college diploma; general course leading to the college diploma in elementary teaching; general course leading to the college diploma in kindergarten teaching. Then there are several courses leading to the college diploma in art, domestic art, domestic science and manual training. Candidates for the first of these courses must be either college graduates or candidates for the degree of A.B., in Columbia University. There is a combined course of study prescribed for the degree of A.B., in Columbia University and the diploma of Teachers' College.

TEACHERS' EMPLOYMENT AGENCIES. Teachers' employment agencies are of two classes, viz: (1) Those that carry on the work in a commercial way and collect fees from teachers for the service rendered in obtaining positions; (2) those managed by institutions of learning, as colleges and normal schools, that obtain positions for their own students or graduates without payment other than general tuition fees. Commercial agencies have existed since 1855 but did not become a prominent factor in the employment of teachers prior to 1890. At the present time there are agencies in most of the prominent cities of the country, some doing a local business, others being national in the scope of their activity. The methods employed by all commercial agencies are quite similar. A teacher enrolls by paying the required fee; making a written statement of his age, education, experience and references. The agent on receipt of the statement writes to the references for further data. When a call for a teacher is received by the agency, two or three of the enrolled teachers best qualified for the place are made application, and the strongest is usually recommended by the agency. The agency's candidate is employed and usually pays the agency a fee of 1/3 of the first year's salary. A well-trained agency becomes an important factor in teachers in the positions for which best qualified. Probably the most service rendered by agencies, however, proper placing of teachers with special qualifications.

HORATIO M. PO

TEACHERS' INSTITUTES. See PROFESSIONAL TRAINING OF.

TEACHING METHODS AND SYSTEMS. Teaching, or the imparting of knowledge by the means of lessons or examples, is a matter of study, evidence, acceptance or rejection of methods through the entire history of education. Talleyrand said that methods of masters of teachers—les méthodes des maîtres. The present educational workers is to make methods to instruction. Two general basic sciences are important in the acquisition of knowledge. The inductive lesson is used in the classroom where associations are made, classes, groups or families of things are classified in use, structure and appearance. A child easily gains a concept of a chair shown a piece of simple furniture with legs, a seat and a back. He may process of time that various articles are constructed, wood, grass, wire, different shapes have been evolved broad, deep—buts strictly, even Toledo is a class. On the hand, a thing that cannot be understood, he cannot classify, is useless. "When a general idea or principle, applies to several or all of the same, so as to explain or give them meaning, is obtained through the study of concrete, individual instances, the process is inductive." Deduction is the opposite: instead of forming one's own conclusions from a series of facts, the student employs those principles already received by his own experience or that of others. The teacher employs the method when he asks pupils to answer questions, to divide problems, to master a subject by referring to rules, laws and axioms. He uses it when he reduces a fraction to its lowest terms: by applying the rule the fraction may be reduced to its lowest terms by dividing both numerator and denominator by their common factors until no common factors remain. In the process of deducing which may not always reach a definite conclusion. Different ones may be tried, some are useful, tried, rejected. "Guiding principle sometimes they are found.

The specific methods of the divide them into three: testing, drilling, teaching. The knowledge provides the instruction point, showing the achievement of the test and its progress, giving oppo
TEACHING OF THE TWELVE APOSTLES

The question and answer method is employed in aiding students to formulate their questions, to aid them in expressing to the best of their judgment, and to form correct conclusions.

This method is being introduced with test success in language teaching, where practice is essential if the pupil is to acquire more than a mere bowing acquaintance with the language under study. Its answers are planned so that the speaker says very little and the pupils a great deal. The question should be correct in form, in meaning, framed in simple terms, comprehended and adapted to the knowledge of the pupil, stimulating to the thought, addressed to the class, and framed so as to draw forth a complete expression.

The question and answer method should lead naturally into the topical method which encourages pupils in freedom of expression and gives opportunity as strength comes to discuss topics and make reports on assigned subjects calling for mastery of the subject and independence of thought. This develops skill in organization of ideas, provides powers of expression and furnishes practice in alertness, systematic thinking, and establishes confidence in one's self. This method can be successfully used in the development of all new topics where the new matter is to be connected to the old in the mind of the learner. It may be a half-formed conversation between teacher and class, directed by the teacher and commanding such full and free expression as will fulfill the mastery and development of the topic.

Lesson plans carefully considered and clearly formulated are of great practical value. In the daily plan the teacher considers the subject matter of the review and advance lesson and the class procedure. The daily plan finds its place in the term scheme and the term scheme is a unit of the syllabus for the year. This daily planning prevents a haphazard course and provides for regular orderly progress. A well-organized plan involves a definite aim, bringing to the aid the proper method, which economizes time and effort.

Results obtained by supervised study have become so successful that a brief survey of this method should arouse the interest of school men in such a way as to lead to its wide adoption. By means of it the teacher is enabled to present the subject matter in such a clear, concise way that every pupil is afforded an adequate opportunity to understand and to master the various daily problems of the subject. It is an elaborate and complete assignment of the next lesson, made so clear that the details present themselves so plainly and logically that all have a maximum opportunity to learn the lesson. It has the advantage of giving aid when aid is most needed, of economizing time and effort and forming correct habits of attack and application of principles.

With the modern trend of social conditions in the city, crowded part time and frequent abundant attraction, some method and supervision should reach into the home to grip parent and student alike. Frequent reports of progress should go to parents; specific direction given in study; students held to the definite performance of certain tasks and an effort made to train in such economy of time and effort as to make school work a delight. This can be accomplished by carefully scheduled program at home and at school.

JOHN MANVILLE SAYLES,
Professor of Education, State College for Teachers, Albany, N. Y.

TEACHING OF THE TWELVE APOSTLES, a part of the Apostolic Constitutions (q.v.) enunciating principles of Christian faith and practice. It was first (1873) discovered by Bryniumus, metropolitan of Nicomedia, in a manuscript of the 11th century and was published in 1875; since which it has been the oc-
TEAK—TECHE BAYOU

easion of much discussion. Consult Harnack, ‘Texte und Untersuchungen zur Alchistlichen Literatur’ (1885). Shad first cut, but when aged, darkens to the tint of black walnut. It is very durable, examples in house-timbers having already survived for hundreds of years, is straight in grain and easily worked. It takes a high polish and if properly seasoned will not warp or split. Teak is used for house-building, furniture and wood-carving and is one of the most valuable woods for shipbuilding, especially for deckings and for backing the metal plates of iron-clads, since it contains a resinous oil, which prevents it from corroding iron; it is also in demand for car-wheels, gun-carriages, railway ties and engineering works. Although the natural supply of teak, throughout its range was great, as it occurred in mixed forests, most luxuriantly in Burma and adjacent regions, it was rapidly disappearing on account of the unceasing demand and lack of replanting. Great Britain has checked this waste by efficient protection and forest-administration in its Indian and Burmese dominions. The timber is mostly consumed in India. The tree is not usually found in pure forests, but mixed with bamboo, which it overtops and which seems necessary for its growth. It requires a light soil with good sub-drainage. The leaves, which are nearly 10 inches long and resemble those of the tobacco, are somewhat drooping and coriaceous and appear as soon as the rainy season opens. They yield a red dye. Teak trees may easily be distinguished for some time during the rains by their broad terminal panicles of flowers, which are small, white and fragrant, on slender branchlets. The seeds are oily, in a hard nut covered with a felt of matted hairs and further enclosed in an enlarged membranous calyx. These feathery panicles render the tree again conspicuous during the dry season, when it is leafless. The seeds are plentiful and would soon restore the forests, were it not for the forest-stores, raging just about the time when the nuts are falling. Many of the seeds, however, are washed down by the first heavy rains of the monsoon, into the valleys, where the trees are principally found. Although many lots of teak have cracks or fissures running up through the centre from the butt, that are partly caused by the fire, the market value of the logs is greatly diminished; that of any other wood except mahogany, depends upon the regular cylindrical shape of the log. This should be in turns of 12 in 1 2 in to or other inequalities, but are taken in the plantation to the butt at about 1 2 in in the trunks. Teak trees may be as much as in 100 ft. tall and a diameter of 12 ft. to attain natural growth and 30 years for hardwood. The timber is exported by the houseboat from the mouths of the rivers. The season is from April to June, as the water rises, and the nut trees.

TEAL, a small fresh-water wild duck of the genus *Querquedula*. Netton, or some close related genus, many species of which occur in various parts of the world. The three North American species are the blue-winged (*Q. caerulescens*), the cinnamon (*Q. q. virescens*) and the common green-winged (*Netton carolinensis*). The former and last are of common occurrence all over North America. The males are noted for their brilliant red plumage, as compared with the sober dress of the little females; hence almost any small gaudy duck is likely to be called a teal in books of unscientific sportsmen and travelers.

TEARS. See EYE.

TEARS OF SAINT LAWRENCE. See SHOOTING STARS.

TEASDALE, Sara (Mrs. F. B. Finlay). American poetess. b. Saint Louis, Mo., 8, 1884. She received her education at pri schools in Saint Louis and spent several years in European travel. Her published works are marked by a charming lyric quality and a rhythmic feeling, include ‘Sonnets to Have and Other Poems’ (1907); ‘Helen of Troy and Other Poems’ (1911); ‘River to the Sea’ (1915); ‘Love Songs’ (1917).

TEASEL, any member of the genus *Dipsacus*, botanically not far removed from the campanulaceae. They are tall plants, often up to 6 ft. tall, with prickly herbs, the most important species being *D. fullonum*, a stout annual, with sessile, lanceolate to pinnatifid leaves, which are opposite and often cuneate. The large head of tubular flowers are gathered in dense terminal, oblong heads, subtended by an involucre and many-fractured. The flower is a few at a time, in horizontal rows. Both bracts and involucre are rigid and tough with spines, the latter being hook-shaped and denoting in fruit. They are then brown and thickly set, radiating from every side of the head, becoming cylindrical and very for raising the nap upon woolen cloth. They are fixed in circular heads on flat cards. The flowers are spiny, and are distributed in a variety of wild, *D. supinum*, which differs chiefly in having a broad, spreading, which are straight.

TECHE (tej) BAYOU, in the southern part of Louisiana, a small tide-water chan-
of Grand Lake, which flows generally by east into Atchafalaya Bay. It was the outlet or the main channel, by which the red river drained into the south of Mexico. The land through which the Teche now flows has been formed from silt brought down by the rivers and by the Mississippi. It contains some of the richest soil of the State. On it are raised large quanti- ties of corn, rice, sugar cane, and cotton. It is navigable to Saint Martinsville, about 100 miles above that point for small boats, and is high water.

CHNICAL EDUCATION. See EDU-

CHNOLoGY, Schools of. Schools of engineering in the United States are of comparatively recent date. The earliest was the Rensse-1 Polytechnic Institute of Troy, N. Y., founded in 1824; then followed the Husseit Training School in Technology, Boston; 1821; the Worcester Polytechnic Institute, Orcester, Mass., 1808; Lehigh University, Stevens Institute of Technology, 1871; Case School of Applied Science, in Cleveland, Ohio. From that time on the number of technical schools has rapidly increased. In 1900 there were 43 technical schools in the United States classified as of the technology by the Commissioner of Education. Among these are privately-endowed institutions, like the Stevens Institute of Technology; State institutions, like the Sit- college of Cornell University; scientific- nents of older universities and schools nents, like the Pratt and the Armour es. The technical schools in Germany are divided as (1) elementary industrial (2) secondary industrial schools; (3) polytechnic institutes. The tendency in the United States is along the same lines, pro- duce and less technical training, in con- with universities, colleges and schools with existing. Many of the State colleges ording in one institution the whole range of applied science. The requirements for admission to the technical schools in the United States are algebra, plane geometry, English literature, the history of the States, French and a knowledge of the n English branches. Some schools re- sult geometry, plane trigonometry, ele- y physics and chemistry and some re- sult in addition to the above. The gen- courses of study pursued are civil engi- mechanical engineering, electrical en- railway engineering, mining engi- chemical engineering, sanitary engineer- architect, pharmacy and chemistry. The of each course is usually four years. engineering forms an additional course University of Maine, University of Michi- one course in the United States. Schools of forestry are connected with the Cornell, and Syracuse University the University of Nebraska and the State University. Horticulture is taught at University, Ohio State University, Iowa State College, University of Nebraska, etc. Domestic art, domestic science, and the fine arts, in addition to steam and machine design and applied electricity, are given at the Armour Institute, Brooklyn, N. Y. At the Armour Institute, Chicago Ill., typewriting, music and domestic art are added to the usual engineering courses. The universities and colleges of the United States have added technological courses to their systems of instruction that it is no longer possible to separate the technological schools. The United States Commissioner of Education has ceased to classify them separately and only a few are known as distinctly polytechnic institutions.

Schools of Agriculture and Mechanic Arts.—The pioneers of technical education in the United States were privately endowed schools of technology, but technical education received its greatest impulse by the "Land Grant Act* and "Morrill Bill* of Congress from the year 1862 to 1890. (See COLLEGES, LAND GRANTS). Under these acts the Federal government has given more than 13,000,000 acres of public lands for the establishment and maintenance of colleges of agriculture and mechanic arts. The name has not always been retained as acts of State legislatures and private benefactions and other causes have led to a change or to an affiliation with State in- stitutions. But as a result, at least one such institution has been established and is now in operation in each State and Territory of the United States, except Alaska. The Interna- tional Typographical Union has established a large school of typography at Indianapolis and the International Printing Pressmen and As- sistant's Union, a school of presswork, near Rogersville, Tenn. Other trade unions are initiating the method and in this way many very important trade schools are developing. Of the institutions that have been organized under these acts, 51 are colleges of agriculture and mechanic arts, having in 1917 over 5,000 instructors; 54,391 white men students; 14,460 white women students, and 4,405 colored men and 6,208 colored women students. Separate institutions for colored students have been established in most southern States. The courses of study pursued in these schools are agriculture, all the branches of engineering, textile engineering (in North Carolina and Mississippi); forestry (in Michigan), and horticulture (in Washington and Virginia). Clem- son Agricultural College, in South Carolina, has a full equipment of cotton machinery for illustrating the manufacture of yarn and woven fabrics. Requirements for entrance differ very greatly in different States. (For detailed information regarding technical education in the United States, see EDUCATION, ENGINEERING; MANUAL TRAINING; TECHNOLOGY; TRADE SCHOOLS). Consult also 'Annual Report of the United States Commissioner of Education'; 'Report of the United States Commissioner of Labor on Trade and Technical Education'; 'Annual Reports of the Society of Mechanical Engineers.'

TECTONIC GEOLoGY. See GEOLoGY —

TECTUMSEH, tē-küm'sē, Shawnee chief: h. near Springfield, Ohio, about 1768; d. 5 Oct.
1813. About 1805 he formed the design of uniting the tribes of western Indians against the whites. He claimed that the land-treaties between individual tribes and the settlers were void, inasmuch as the land was the common property of all the tribes and could not be alienated by any one of them without the consent of the others. The British agents denied his dissatisfactions, which were increased by the ejection of Indians by settlers. Gen. W. H. Harrison (q.v.) warned him to desist, and concluded with a parley with him without result near Vincennes, Ind. He was aided in his plans by a brother, Tenskwatawa, who was reverenced by the Indians as a prophet. Tenskwatawa directed the attack at Tippecanoe (q.v.) Nov. 4, 1811, though he remained on a hill during its progress. Tecumseh was not present. He invited the Creeks in their futile revolt, joined the British, was made a brigadier-general, led 2000 Indians at the siege of Fort Meigs, commanded the right wing at the Thames and was killed there. He possessed great qualities of leadership. Consult Drake, "Life of Tecumseh."

TECUMSEH, Mich., village in Lenawee County, on the Kaisn River and on the Lake Shore and Michigan Southern and the Chicago, Jackson and Missouri railroads, about 35 miles northwest of Toledo and nine miles northeast of Adrian. It is in an agricultural region noted for its fruit, especially peaches. The chief manufactures are flour, furniture, wagons, carriages, brick, tile, paper, lumber, foundry and machine-shop products and dairy products. It has a high school, graded schools and a public library. The two State banks have a combined capital of $70,000. Pop. about 2,332.

TECUMSEH, Neb., county-seat of Johnson County, on the Big Nemaha River and on the Burlington and Missouri River Railroad, about 45 miles southeast of Lincoln and 60 miles south of Omaha. It is in a rich agricultural region. It is the commercial centre of a large portion of the county; the chief shipments are grain, livestock, vegetables and fruit. There are churches, a high school, four public school buildings and a public library. There are two banks, a national and a State, with a combined capital of $100,000. Pop. 1,748.

TEES, tész, a river in northern England, which rises east of Cross Fell forming along its entire course the boundary between Durham and the North Riding of Yorkshire, passes between Barnard Castle, becomes navigable between Delph and Yarm, and, after flowing a distance of 70 miles, empties into the North Sea at Middlesbrough, forming the Tees Bay.

TEETH, hard structures developed in the mouth and adjacent parts of vertebrated animals and concerned in the obtaining and mastica-
tion of food and secondarily in a variety of other functions. "They present," says Owen, "many varieties as to number, size, form, structure, position and mode of attachment, but are principally adapted for seizing, tearing, dividing, pounding or grinding the food. In some species they are modified to serve as formidable weapons of offense and defense: in others, as aids in locomotion, means of anchorage, instrument of or cutting down wires or for transporting and working of building materials. They are characteristic of age and sex; man they have secondary relations, subs to beauty and to speech. Teeth are always related to the food and habits animal and are, therefore, highly interest the physiologist, too, for the reason, important guides to the natural classification of animals." For further mention as to the development of the forms of teeth in relation to use, see TOOTH.

Teeth are a production of skin, and gous with the scales of fishes, and various hardenings of the surface; in some of the lower invertebrates there is angradation from one to the other. In an class, the birds (q.v.), they are now absent, their functions being performed by the covering of the jaws (bill) or by a beak, or both; but in the earliest extant they were present in both jaws and had resemblance to those of reptiles. Turtle and many amphibians are toothless; some of the inferior mammals teeth are only as embrionic rudiments, which did not assert themselves before or soon after birth. Many small hardened structures in the worms, echinoderms, mollusks, insects and other invertebrates, which are more or less concerned in biting, are popularly spoken of as teeth, but, strictly speaking, should be otherwise designated. In the present article will treat of the teeth found in the mouth of man and the vertebrates, where they arise from the covering of the jaw-bones, each root socket or sockets of its own formed by the maxillary bone.

Structure of Teeth. A tooth begins in embryonic life, by the development of the mucous membrane of the gum of a modified epithelial cells which dip into the substance of the gum and form the germ of the tooth, which will furnish enamel needed. Below that there next a mass of special tissue which takes the form of the future tooth. In due time it becomes calcified upon the surface, and this process ceases, downward and inward, until all substance of the papilla has been chiseled away, and the dentine remains filled with growing tissue (pulp) with blood and nerves. This is the principal constituent of the greater part of a tooth, and is seen to best advantage in the massive ivory of the tusks of the elephant, and consists of an organic and impregnated with mineral (chiefly phosphate of lime) disposed in the form of minute hexagonal columns, perpendicular to the plane of the surface of the crown receives the on the opposing tooth, and are horizontal in the opposite tooth, and are the pressure of the teeth. The roots also receive their support from the remains of the pulp, which circulates by anatomical
TEETH

which in mammals never normally occurs before birth. This appearance in some, as the seals, may take place all at once; but in most cases occurs at intervals, the front teeth usually showing before the back ones, which sometimes are not cut (for example, the "wisdom teeth" in man) until several years later. In man and higher mammals two sets of teeth are developed: the early, milk, or deciduous teeth, and the permanent set. Such forms are, therefore, named diphyodont; while those in which one set only is developed are named monophyodont. When more than one set occurs, those of the second are developed in precisely the same place and manner as the first, except as to certain details of the enamel germs. The milk or temporary teeth are gradually displaced from below by the upward growth of the permanent teeth, the fangs of the milk teeth being absorbed, and the latter falling out as their successors are more fully developed. This arrangement is adaptive to the growth of the animal's jaws, among other advantages. The milk-set in man consists of twenty teeth the tooth-sac, the inner layer of the diente, like bone, the crura cement, on the external surface of the tooth.

It is often found only as a thin surface of the root, which develops as the tooth grows, forcing the tooth root and above the gum; but some the molar teeth of the horse, ele- masteodon, is a structure which is important part covering and filling eristines between the folds of the dentine like true bone in general. Meanwhile the epithelial cells of the layer of the skin over the tooth-depositing upon the diente of the of the tooth, which is to be exposed, eyn hard bluish white, translucent, layer, composed of about 96 per neral matter, called the enamel, and resist the wear to which teeth are in their work. It is the hardest known substance of any animal form, but reducible to the simplicity of the simpler and milk teeth, or exposed part of the crown, is of the conical form and persistent, and continues to line the base of the tooth, which throughout life to compensate for away at the tip. These teeth are "rootless." The other type, ex- man, is called "rooted," and in this the "crowns," or exposed part of the been fully formed, the pulp within part that just beneath the sur- e gum, begins to fill with dentine, its downward growing pointed mass, or "fang," which at last is solid ex- ward as a cone protruding from the remainder of the pulp persists, ap- with nervous filaments from the cranial nerves. Various intermedi- between these two types exist. One type is of a chisel-like shape, to many chisel-like or massive iated forms, all of which are den the germ, and before the tooth appearance above the gum or is "cut,"

26-21
the crown is crossed by parallel ridges, which are greatly varied and complicated, up to the huge molars of the elephant family; in these cases the ridges are formed by partition-like infoldings of the enamel and the interspaces are filled with cement. Such a tooth wears away at the surface, the different density of the layers of the substances of which it is composed—enamel, cement, and dentine—causes them to wear unequally, the hard enamel ridges projecting beyond the others and thus, as Flower says, "giving rise to a grinding surface of great mechanical advantage." The pattern of these ridges is characteristic of species; and by the changes of pattern which occur as they wear down, the age of the animal may often be closely estimated, a fact constantly utilized in the case of horses. This infolding of the enamel reached its highest complication in the curious "labyrinthodont" teeth of the ancient stegocephalian reptiles.

The dentition of any animal is expressed by a dental formula. That of man runs thus:

\[ 2-2 \quad 1-1 \quad 2-2 \quad 3-3 \]

This means that the incisors (1.) number two on each side of each jaw—the numbers above the sub-buccal line corresponding to the teeth in the upper jaw, those below the line indicating those of the lower jaw; while the further subdivision of the teeth above and below the line is meant to indicate the numbers in each side of each jaw respectively. The other signs and numerals, therefore, read that the canines (C.), premolars (P.M.) and molars (M.) number two, four and six in each jaw; making a total of 32 teeth. Similarly the dental formula of a ruminant (r.v.) such as the sheep would run thus:

\[ 0-0 \quad 0-0 \quad 3-3 \quad 3-3 \]

It is presumed by this notation that each tooth has its strict homologue, in all kinds of mammals at least; and if any are missing their character or name may be accurately defined. This theory encounters difficulties, for example, in comparing the dentition of marsupials with the higher mammals; but it serves conveniently in the description of ordinary animals.

Among the lower vertebrates teeth appear in great variety, as to number, form and functional modification. Those of fishes and fish-eating animals as the dolphins, are simple sharp curved cones, useful in seizing and holding their slippery prey, which is usually swallowed whole. In fishes and most reptiles the teeth are usually attached by ligaments, and shed and renewed, not once only, as in mammals, but frequently during the whole course of their lives. In sharks the teeth are placed in a common groove, and row after row may be developed; as in evolutions, fishes as the front and older teeth are worn away or detached. Fishes and amphibians may have teeth in two rows in each jaw, and also on the back part of the mouth and on the skull. In the ruminants we have the "sheep teeth," pharyngeal bones, soles of the mouth and in other situations. The lower vertebrates have the teeth acted on in various ways by the jaws, and are implanted in sockets as in man. In reptiles, as a general rule, the base of the tooth is anchoylosed to the bone which support it. The completion of a tooth is soon followed by preparation for its removal and successive faculty of developing new teeth germs apparently unlimited in this class. The teeth of crocodiles grow continually, on growing inside the pulp cavity of the tooth, displacing it. In many lizards teeth are anchoylosed to the summit of the jaw (acodont), or to the outer side of the pleurodont. Repartition teeth sometimes undergo great modifications, as in the poison fangs of vipers and rattlesnakes. Extraordinary modifications among men are seen in the horn pyphos-teeth of the bill; the entire absence of teeth of some states; the transitory teeth of the balenin; succeeded by whalebone; the "horn" of whal, the tusks of the elephant, walrus, boar, etc., each in relation to peculiar.

There is also a close connection between articulation or joint of the lower jaw as nature of the food used by the animal, in purely carnivorous animals, in which teeth simply tear and cut the food, no grinding is required, and the jaw is capable of a simple hinge-motion; while in herbivorous animals the joint is constructed to allow of extensive side to lateral motion of the lower molar teeth the upper. In man both the form of this joint and the general character of the point to an intermediate position in relation to the food, and form a physiological argument for the mixed diet which general customs have decided to be most natural to our species.

Diseases of the Teeth.—Decay (car) by far the most common of the diseases which affect the teeth, and consist in a gradual progressive disintegration of the tooth substance. Among the chief predisposing causes are hereditary defects of quality, imperfect calcification; pits and grooves in the gum produce a overcrowding of the teeth, facilitating introduction of particles of food between them, and thus causing disorders affecting the digestive system. Decay is usually caused by lactic acid generated in the mouth by the fermentation due to micro-organisms. Decay usually begins in a groove in the enamel or between the carious points forming a lodgment for the development of the organisms. Once the enamel becomes penetrated the decay proceeds more or less spreading laterally beneath the enamel and toward the pulp. The more the structure of the tooth the more does the decay penetrate in the direct of the pulp, though its process is not such its tendency to spread is less. Caries is common in early life, by far the great number of cavities making their appearance between the ages of 6 and 18. The treatment can only be undertaken by the and varies with the extent and character of the disease.

Periostitis and Alveolar Abscess is an inflammation of the periostum which covers the roots of the teeth and lines their sockets. By far the common cause is the presence of a
ous products of which cause violent
ion at the end of the root. When
osis has fairly set in, and its usual
iment, alveolar abscess, are perhaps
painful affections to which the teeth
ar abscess may be defined as a sup-
around the root or roots of a tooth. 
are those of periostitis which pre-
thashop the cavity nature in indicating the formation of mat-
in the surrounding bone. The face,
glands about the neck, swell, and the
hibit tenderness on touch. The dent-
ces its way through the bone to reach
ge of the gum at the point of least re-
which is most often opposite the end
it or roots (this is popularly known as
il). With the escape of pus there is
abatement in the intensity of the pain,
early disappears in a few hours and
ng in a few days.

ition and Difficult Eruption.—It is
oon to find certain of the temporary
ly set in the adult jaw, and occupying
of the gum. One of such abscesses
ent tooth is usually present in the
jaw, but it has been retarded in
by being too deeply embedded in the
section may also be due to abnormal
of growth. Such teeth may appear
after all the others are lost, and the
lying them has been absorbed and so
hem. When these cases do occur they
nsile for the popular but incorrect
third set of teeth. An impacted tooth
ves rise to any trouble, unless it be an
lower wisdom, particularly the latter.
g of these teeth is sometimes accom-
distressing symptoms, which may be
l for months or years, unless they are
by extraction of the tooth. This con-
usally due to imperfect development.
The tooth usually takes its natural
ition, but, being wedged in between in
ment and the ascending portion of
behind, or to such diseases as mercury or
table. The overlying gum is apt to
by the occlusion of the opposing
average jaw; inflammation is there-
up, and being maintained by biting
id to the surrounding parts. Swallow-
less painful and the motion of the jaws
When it is evident that there is in-
accommodation in the jaw for the
tooth it should be removed.
mination of the gums, though not a dis-
the teeth proper, is one of the most
as of the premature loss. It may
a constitutional causes—chronic dys-
matism or gout—or from the ad-
on of such drugs as mercury or iodid-
um. Most often, however, it results
presence of tartar about the necks of
, and lack of thorough cleansing.
e to constitutional causes, their ap-
remedies are called for; but when
presence of tartar, this deposit should
lly removed.
ache.—Other diseases of the teeth are
only suffered, and more obscure. The
dentist should be sought on sus-
ta from a large abscess in the gums of
aching tooth is a symptom of dis-
ease which requires instant attention. When
due to carries with or without simple exposure
of the pulp, the attack is brought on by taking
hot or cold, sweet or acid fluids, and is seldom
of long duration. To afford relief in such cases
these, gently wash out the cavity with a solu-
tion of carbonate of soda; then, drying it care-
fully with a piece of cotton-wool, take a very
small pellet of wool dipped in eucalypthus oil and
placing it in the bottom of the cavity; then place
piece of cotton wool large enough to
fill the cavity and saturated with the following
solution: one dram of mastic in one and
half ounces of eau de Cologne. This should be
changed daily. When the pain is caused by the
forming of an alveolar abscess the tooth will
be found insensitive to change of temperature
but very susceptible to pressure. The patient
now becomes feverish, and the pain, which is
at first of a dull heavy character, becomes more
intense, throbbing, and continues, till pus has
been formed and discharged through the gum.
Provided the tooth is likely to prove useful and
the patient cannot consult a dentist, the gum
should be carefully painted with tincture of
iodine, or the old-fashioned plan of putting a
roasted fig over the root may be resorted to;
at the same time it is well to give an aperient
such as Epsom salts, followed by a full dose
of quinine—six to eight grains for an adult.
Great relief follows this treatment, which is, of
course, only temporary. If an abscess shows
signs of pointing on the gums it may with ad-
antage be lanced. Poultries should never be
applied to the face, for heat tends to draw the
pus outward. Abscesses in connection with the
lower wisdoms often assume a very serious
character unless cut short by extraction of the
tooth.

Hygienic Care of the Teeth.—Many of the
diseases of the teeth and gums might be pre-
vented or greatly retarded by proper attention
to the cleansing of these organs. The imple-
ments best fitted for this purpose comprise the
quill toothpick, waxed silk thread and brushes,
with suitable powders. The toothpick ought to
be used after every meal, but it should be sup-
plemented by the use, between the teeth, of floss
silk, which will remove deposits accumulating
where contiguous teeth touch. The brush is
used to remove all deposits solid and mucous,
and it gives the teeth a bright and polished ap-
pearance; its mechanical friction, too, stimulates
the gums to more healthful action. An excel-
lent tooth powder is composed of precipitated
chalk, two ounces; light magnesia, two ounces;
oil of cinnamon, eight drops; thymol crystals,
four grains; otio of roses, 10 drops. The teeth
should be brushed twice daily, in the morning
and in the evening. The manner of using the
brush is more important than many people sup-
pose. The general method is to brush horizon-
tally, but a moment’s reflection will show that
this leaves untouched the very situations most
in need of cleansing. The brush, used properly,
should be pressed against the teeth and the
handle rotated so as to make the bristles sweep
together and between and over them in this case
with an up-and-down motion will thoroughly
cleanse the interspaces; the inner surfaces of
the back teeth are best cleaned in a like man-
ner, while the corresponding parts of the upper
day and lower incisors are easily cleaned by
vertical drawing movement. The brush should
TEFFT, Benjamin Franklin, American Methodist Episcopal clergyman, college president and diplomat: b. Floyd, N. Y., 20 Aug. 1813; d. Brewer, Me., 16 Sept. 1895. He was graduated at the Wesleyan University in 1835 and in 1839 entered the Methodist Episcopal ministry. He held pastorates at Bangor and at Boston and in 1843-46 he was professor of Greek and Hebrew at Ashbury, Ind. (now De Pauw), University. He edited the Ladies' Republic, 1840-52; was president of Greensboro College, Lima, N. Y., in 1851-54, also editing the Northern New Yorker in 1852-54; and held pastorates at Bangor in 1858-61. He was appointed United States Consul at Stockholm and acting minister to Sweden in 1861; and in 1864 was made commissioner of immigration from northern Europe for the State of Maine. In 1873 he edited the Northern Border at Bangor. Author of 'Prison Life' (1847); 'Hungary and Koszuth' (1852); 'Webster and His Masters' (1853); 'Methodism Succeasful' (1860); 'Evolution and Christianity' (1865), etc.

TEGEA, Arcadia, city of ancient Greece whose site was near the modern Tripolitsa. It was situated on the southern portion of a plateau nearly encircled by mountains, the northern half being occupied by Mantinea. It was a highly fertile region, but was subject to floods because of an insufficiency of outlets through its mountain barriers and together with Mantinea was dependent upon underground drainage conduits. This common dependency was a cause of frequent wars with Mantinea while Tegae's natural position controlled chief roads leading from Laconia to Argos across the Isthmus, and the Spartan League but did not do otherwise deprive it of its independence. It was a member of the Arcadian Confederacy after the battle of Leuctra in 371 B.C. and later belonged to the Aetolian League, which held a place of importance after the Roman conquest of Greece, but in 404 B.C. it again became Sparta's ally. It was vacated in 1899. The excavation of its ruins was begun in 1879. Its most important building was the temple Athena Anea, rebuilt by Scopas in 395 B.C. It was a combination of Doric, Ionic and Corinthian architecture, 72 by 154 feet; the sculptures also were by Scopas and represented the slaying of the Calydonian Boar and the combat of Telephus and Achilles. While these are in fragments they were evidently in the best manner of Scopas. Consult Curtius, E., 'Peloponnesos' (1851); Mendel, G., 'Bulletin de correspondence hellénique' (Vol. XXV, 1901); Gardner, E. A., 'Fragments of Greek Sculpture' (1815).

TEGENSEE, Germany, village and mountain lake resort in the province of Upper Bavaria, on Lake Tegernsee, 32 miles southeast of Munich, 2,300 feet above sea-level. It has a castle which originally was a monastery founded in 719; a parish church of the 13th century; and an orphanthropy established by Duke Charles Theodore of Bavaria. It is much frequented as a summer resort, the lake and the fine mountain scenery offering many attractions. Pop. about 1,900.

TEGNER, têng-nér', Essaas, Swedish poet: b. Kirkerud, Wermland, 1782; d. Vesle, Smaland, 1846. He was graduated at the University of Lund in 1803, became (1812) professor of Greek literature and member of the Swedish Academy, was ordained priest and in 1824 was appointed bishop of Vesle. As a poet he struck out a new path in Swedish literature. His first attempts did not meet with much acceptance, but at length he came to be regarded as the greatest poet of Sweden. His poetry is characterized by inexhaustible vitality, rich, fancy and lively feeling. His most notable work and the dream on which the whole of his work is based was the epic, translated into English. Its great value lies in its accurate reproduction of the legends that are included. He also wrote the national songs and 'Children of the Lord's Supper,' translated by Longfellow. His works were collected and
by Böttiger, his biographer (1847–
ec ed. 1882–85). The later years of
were spent in a retreat for the insane
a paralytic couch. (See Firth's

province of Teheran is divided into six
aining much fine agricultural land-
ous villages, two of which are held in
the British and Russian governments.
ly. There are fine coal fields in Kas-
streets in abundance in rich Veramin
s watered by the Jâfrdâ River. The

chief products are fruit and grain, wheat, barley
and rice. A railway, passing through Mesol-
potamia, connects the Mediterranean with the
Black Sea and the Gulf of Persia. It furnishes
an all-rail route from Calcutta to the British
Channel and shortens the distance from Te-
herân to Constantinople by two weeks.

TEHUANTEPEC, tâ-wân-tâ-pék', City of,
situated in the state of Oaxaca, Mexico, 18
miles from the Pacific Ocean, is the centre of
a fertile and productive country in which coffee,
sugar and other tropical products are largely
grown. It has a considerable trade in cotton
which are raised on adjacent lands. The city
is an important station of the new inter-oceanic
railway. Pop. about 18,000, including a large
number of persons of Indian extraction.

TEHUANTEPEC, Isthmus of, comprises
that section of the Republic of Mexico within
the states of Vera Cruz and Oaxaca where the
Gulf of Mexico and the Pacific Ocean approach
nearest one another, the distance from the
mouth of the Coastzacoalcos River, on the east,
to the port of Salina Cruz, on the west, being
437 1/2 miles. This point is one of the few
stances where a depression exists in that
vast chain of mountains which extends from
north to south along the western shores of both
American continents. At Tarifa, the lowest
point of the summit level, the altitude is but
754 feet above the sea. Cortes, searching for
a safe harbor for his ships, discovered the
Costaacoalcos River, wide and deep where it
empties into the Gulf, and pronounced it
the finest in Mexico. Informed of the narrow
strip separating the two oceans, the Spanish
was evidently impressed and at once grasped
the idea of inter-oceanic communication at this
point. With prophetic insight and influenced
by the enormous advantages which were cer-
tain to result to the isthmus by the construc-
tion of a ship canal, Cortes located a vast land
grant, presented by his sovereign, in close
proximity, and chose for a title the Marquis of
Tehuantepec. His successors caused super-

duceal surveys of the coast to be made and
were convinced that no serious obstacles pre-
vented building a ship canal and, considering
the diminutive proportions of vessels at that
time, the enterprise was well within the engi-
neering powers of the time. It was proposed to employ native slave labor in its
construction. Political and strategic considera-
tions prevented the Spanish government from
ever encouraging the enterprise. When Mexico
became independent it was too much engaged
in restoring order to give attention to internal
improvements and it was not until 1842 that a
cession for opening a line of communication
by canal or railway, or both, was granted to
Don Jose de Garay, a citizen of that country.
Accurate surveys were made and a practicable
route selected, but, for lack of financial en-
couragement, the concession was afterward sur-
rrendered. Until 1852 capitalists of the United
States betrayed no special interest in the enter-
prise, but when the extension of railroads from
California and Oregon was assured, the im-
portance of more rapid communication between
the East and West was quickly realized. In
that year the Barnard and Williams expedition
was dispatched to the isthmus to survey a route
for an inter-oceanic railway. These explorers
made very careful surveys of the entire route and pronounced the enterprise perfectly feasible, but were subsequently ordered out of the country, the introduction of American capital not being encouraged by the Mexican government, so soon after the war between the two countries. In 1871 the expedition under Commodore Shufeldt was dispatched to the isthmus by the United States government to make a final survey and finally determine whether a ship canal could be built over the route or not. The result of the survey was a decision that a ship canal, capacious enough for modern vessels, was not practicable owing to insufficient water supply for the upper levels. This expedition also reported adversely to the lagoons, which indent the western coast and were considered the natural location for a terminal harbor, on account of certain unfavorable physical conditions there existing. A new location for a terminal was chosen at Salina Cruz, a few miles westward of the mouth of Tehuantepec River, where greater depth of water was afforded, as well as more complete shelter from the prevailing winds.

The Eads Ship Railway.—In 1883 James B. Eads, a distinguished engineer, conceived a plan for the construction of a railway over the isthmus by which vessels of the largest dimensions could be transported by rail at a speed of 10 miles an hour. The details contemplated the deepening of the Coatzacolco River for a distance of 20 miles to the town of Minatitlan, which was to be the eastern terminus. The western terminus was to be at Salina Cruz. At these points giant pontoon docks were to be located and three lines of railway of standard gauge connected the two points. As a vessel sailed over the psoaons it rested upon a railway carriage, secured from all strain by ingeniously contrived supports. Raised to the level of the tracks the carriage was connected to three powerful locomotives and with its load carried across and deposited into the dock at the other terminal. The length of the railway was to be 165 miles, with a very substantial roadbed and with not greater than 20-mile curves. Where abrupt curves existed, they were to be avoided by turntables at five different points. Vessels in transit were thus always in a straight line. The plan after being subjected to much criticism was at last endorsed by the highest engineering authority in the world and would probably have been built but for the death of its projector in 1887. Its cost was estimated at $75,000,000. Mexico granted 1,000,000 acres of public land in its aid. Thus for three and a half centuries every plan conceived for the attainment of communication over the isthmus having failed, Mexico determined upon the construction of the railway as a national work and spent $30,000,000. Finally about 1897 the railway was opened to a length of 122 miles, but the impending opening of the Panama Canal greatly reduced its importance.

TEIXEIRA DE MATTOS, tá-shär‘ē dā mà’tōs, Alexander Louis, English journalist and translator: b. Amsterdam, Holland, 9 April 1865. He settled in England in 1874, was educated at Beaumont College, Old Windsor, and entered upon journalism. He has been for some time as correspondent and as associate editor on various periodicals and has published translations of Melani van Java’s ‘Resident’s Daughter’ Zola’s ‘Curée’; ‘Memoirs of Chateaubriand’; Zola’s ‘Grande Illusion’; Josine Holland’s ‘Leida’; ‘The Cradle’ (from the Flemish) and some of Maeterlinck’s tales.

TEJUI, or TEQUEXIN, a large lizard (Tupinambis teguixin), inhabiting tropical America. The upper parts are deep-black mottled with green and yellow; the sides show two rows of white spots; and the under parts are yellow, marked with black stripes. A full-grown specimen may be three feet in length, mostly tail. These lizards frequent forests and plantations, are carnivorous and their strength and speed enable them to overpower a number of animals, including barnyard chickens and eggs. They are consequently hunted, not only as pests, but because they are themselves good to eat. They dwell in burrows, lay hard-shelled eggs in the ground and defend themselves by vigorous lashing of the tail. They have some resemblance to the Egyptian Parauus gives them the borrowed name of salvator in some places. This lizard represents an American family, the Tejide, with long forked tongues largely covered with scale-like papillae. The teeth are solid and implanted almost on the edge of the jaw and are therefore intermediate between acrodont and pleurodont. The body is covered with small scales (osteoderms are absent) or the skin may be simply granular above; the under surface is covered with larger scales generally arranged in transverse rows. This large family, says Gadow, “which comprises nearly 40 genera with more than 100 species, exhibits great diversity of form. Some are inhabitants of forests and are arboreal, while others are strictly terrestrial, preferring hot and sandy plains, or they dwell below the surface and are transformed into almost limbless and scaleworm-shaped creatures. Representatives of the family are spread from Texas and Utah to the borders of Patagonia.

TEKELI, té-kēl‘ī, or TOKOLY, té-kol‘ē, Emmerich, Count of, Hungarian noble: b. about the middle of the 17th century; d. Vienna, 1705. His father had headed an insurrectionary movement against Austria and he himself was chosen by the Hungarians in 1678 their commander-in-chief. He broke into Upper Hungary, captured several fortresses and towns, devastated Moravia and penetrated into Upper Austria. The emperor consented to redress several grievances at the Diet of Oedenburg (1681); but the insurgen were not satisfied and refused to lay down their arms. Tekeli now put himself under the protection of the sultan Mohammed IV, by whom he was declared king of Hungary. A war between the emperor and the Porte ensued in which the Turks advanced (1683) as far as Vienna, but were totally defeated before that city, by John Sobieski, king of Poland (12 Sept. 1683). The campaign continued without success. He fell under the suspicion of the
who sent him a prisoner to Adrianople. Meanwhile his wife was besieged by
trians in the castle of Munkács, where out for three years, until she was com-
y fame in the face of the.der. In the same year he was con-
s discovered the groundlessness of picions of Tekeli and he once more re-
e support of the sultan, who designated
n of Transylvania. He penetrated t country and routed the imperial gen-
90, but in the same year he was con-
y Louis, margrave of Béren, to retire. ened in all the struggles between Aus-
 Turkey till 1697, when the Peace of
 was concluded, in which Turkey re-
the cause of the Hungarians. Tekeli
red to the dominions of the sultan, who
 upon him several estates, with the
 prince of Widdin.

elechirograph, invented by Gruhn, a rad-
d here receiving apparatus is used. The
 currents influence two electro-mag-
 etic in the form of a small coil on the
 mirror; a light ray from a small incandescent
 lls upon the mirror whence it is re-
 o a sheet of sensitized paper. The mir-
 ead by means of cement to a small
t in the form of a small coil on the
 rest upon a set screw upon which the
can oscillate. Beneath the two other
 extend two armatures subjected to the
 of the electro-magnets. These arma-
degree oscillations of the receiving and the
rent movements of the transmitting pen-
cil; they are carried by flat springs, and the os-
cillations are given to the iron plate and, of-
course, to the mirror fastened to it. Before the
message can be delivered the receiving shee
must be developed; the apparatus for this is
: when the message is completed a small
lectric motor operated by an independent bat-
tary in the receiving room is set in motion; this
motor works a train of wheels or rollers which
draw the portion of the film written upon by
the light ray through a developing bath and out
again through a pair of rubber drying rolls.
The completed message is delivered in less than
35 seconds after the transmitting operator has
placed his pencil in its rest.
TELECHIROGRAPH. See TELAUTO-
GRAPH.
TELEDU, a badger (Mydas meliceps) of
Java, which is skunk-like in its habits, and in
the copious and far-reaching vuleness of the
secretion in its anal glands.
TELEGONY, the inheritance by offspring
of the characteristics of some previous mate
one or both parents. That such a character
 has long been the belief of breeders of live-
 stock, who spoke of the phenomenon as "throwing
back." Until about 1890 scientific men gen-
erally lent their support to this theory, although
Weismann long ago expressed serious doubts.
About 1895 Ewart began a series of careful
experiments at Penicuik, near Edinburgh, Scot-
land, and certain others were undertaken in
Germany and Brazil, the outcome of which was
to show that the phenomena noticed were
evidences of atavism, or reversion or variation,
and that no such a thing as telegony existed.
See HEREDITY.
TELEGRAPH BATTALIONS. The gen-
eral duty of signal troops is to collect and
transmit information, to assist in providing se-
curity for troops, to assist in directing fire
attack during combat, to provide means for
ready verbal and written communication be-
 tween distant commanders and troop leaders,
to facilitate the transmission of verbal and
written messages and orders, to insure the
secrecy of such messages when necessary by
means of codes and ciphers, to exercise super-
vision over the character of matter transmitted
by means under its control, and when circum-
stances make it necessary, to fight in order to
accomplish any of these objects.
The work of signal troops assigned to lines
of information in war varies with the nature
of the lines which they control, viz. (1) The
maintenance and operation of electrical lines
of information from the capital of the nation
to the headquarters of the armies in the field.
(2) The construction, maintenance and opera-
tion of the radio stations and central permanent
telephone and telegraph lines connecting the
headquarters of each army in the field with
its various divisions and other units, and the
necessary camp telephone and telegraph lines
within these armies. These lines are included
in the zone of the advance.
The signal organizations assigned to both
these classes of duties are called Telegraph
Battalions. In the first class they are distrib-
uted along the lines and at stations as required
for construction, maintenance and operation
without being supplied with the special tech-
technical equipment and transportation required in the
field. They operate the telegraph cable and radio offices and the telephone systems with substantial aid from the same apparatus used in times of war. These systems have taken the seat of government through the zone of the line of communications up to army headquarters. For maintenance, repair and extension the material and equipment supplied is the same as in commercial practice.

In the second class of work signal troops must install and operate lines under quite different conditions. The poles and wire must be light and the instruments of special design for a service unlike that encountered in commercial practice. For administrative purposes the telegraph battalions employed in this class of work are organized into companies, and these in turn into sections, each equipped with supplies and transportation for installation of a complete telegraph or telephone system in the mobile units with which they serve. The telegraph battalion prescribed in the tables of organization consists of two companies. Each company has six sections—three telegraph and three telephone. A telegraph section is equipped to install 20 miles of wire on lances with three telegraph offices. The equipment is carried in one wagon of the escort type and one lance truck. The 10 men of the section furnish the linesmen, operators and the transportation for the construction, maintenance and operation of 20 miles of line. The telegraph equipment and personnel of the company is sufficient for 40 miles of line and that of the battalion for 120 miles. A telephone section is supplied with material for the installation of a telephone system of 20 telephones connected with a field switchboard and 20 miles of insulated wire laid on the ground or supported on lance poles. The equipment is carried in two telegraph wagons of the escort type and the lance truck. Twenty-one men make up the switchboard operators, linemen and messengers needed. The equipment of the telegraph battalion is necessarily bulky and heavy and its mobility in general is limited to that of the supply train.

**TELEGRAPHPHONE**, a recording telephone, the invention of Valdemar Poulsen, of Copenhagen. He devised a magnet of sufficient delicacy to limit the magnetizing of a metal plate to the direct point of contact, no matter how minute that point might be. His magnet, in tracing its course over a steel disc, magnetizes only the molecules of the steel with which it comes into direct contact. Thus localized and defined, electro-magnetism becomes controllable. The result was a mechanism that recorded the sounds given into a telephone receiver, on discs that could be mailed like letters, and reproduced by the recipient. This interesting machine failed of commercial success. Consult Scientific American. Sup. (Vol. I. XIll, No. 10, 28 Feb. 1902).

**TELEGRAPHY.** The word telegraphy is derived from the Greek, tele, "far off," and graph, "to write." In the modern practice of telegraphy, however, the term has a wider meaning and is used to signify any means by which intelligence is transmitted to a distant point by means of wires. In this sense the word would also include the transmission of speech electrically to a distance, but inasmuch as that highly important art possesses its own appellation (telephone) such use of the word is unnecessary.

From remote times methods of communicating intelligence to a distance have been employed for purposes of war and defense. The Greeks were perhaps the first to adopt systematic methods of telegraphing, and a description of a telegraph system that was employed 300 B.C. is to be found in the writings of the Greek General Polybius.

**Polybius Telegraph.**—The operation of this system was as follows: At each station there were two walls about seven feet in length and about six feet in height, separated by a space of three feet. At night or more torches, as desired, but not exceeding five in all, were placed on top of the walls, and certain combinations of the torches represented the letters of the Greek alphabet. A tablet showing the combinations of torches for the various letters was provided at each station. For instance, two torches on the right-hand wall and three on the left wall would represent the combination g which was on the right wall and four on the left, y, and so on. When it was desired to signal a station, two torches were set on a wall, which signal was answered by a similar arrangement of torches at the other station. The operator then proceeded to spell out his message by placing the torches in the required combinations, one letter at a time. The tablet mentioned was divided into vertical and five horizontal rows of squares, each letter of the alphabet being allotted a certain square, beginning at the upper left-hand corner with A, and running horizontally across the tablet. Any letter could thus be found by giving the number of vertical and horizontal rows at the intersection of which the square allotted to that letter. For instance, the letter Y would be at the intersection of the fourth horizontal and the fifth vertical rows. The code thus formed, in a more or less modified form, is in use today by the military departments of various countries as a means of telegraphing maps of a locality.

**Fire and Smoke Signals.** The use of fire by night and smoke by day has long been practiced by even the most uncivilized races, as a means of communicating intelligence to a distance. In numerous places in this country there still remain evidences of this practice by the aborigines, in the shape of mounds on hill tops and other points of advantage, on which the accumulated ashes of beacon fires of hygroscopic years may be found beneath the roots of trees of gigantic size. In the country between Chillicothe and Columbus, in Ohio, for instance, may be traced over 20 such mounds, so related to one another that if all the trees were removed fire signals might be transmitted from one end of the valley to the other in a few minutes. To this day the Indians of North America practise this method of approach of enemies in their territory; and up to within a comparatively short time such fires were the most favored methods of signaling the approach of an enemy in Great Britain and other European countries.

**Semaphore System.**—It was not until the end of the 18th century that any comprehensive
maling was employed in Europe or in ry. The plan then introduced was a as the Chappé semaphore system of

This semaphore resembled the sema-

common on all railways to-day, con-
am upright post, on the top of which
arms or blades are pivoted, but in è semaphore the arms were arranged current from those of the ordinary
technique. Thus the crossarm on the top
was 14 feet in length, and on that
arm a shorter arm was pivoted
ages to the longer arm. By a sys-
tese and pulleys these arms could be
ed by the operator and placed in
cent positions, certain positions of
representing given letters of the al-
thence by appropriately placing the
manipulator could spell out words
ages which an operator at a distant
d read and, if necessary, retransmit
station further on. These sena-
re placed on substantial stone towers
as apart ranging from six to 10 miles,
se spread rapidly throughout Europe,
, Germany and Russia especially the
widely used. For example, a string
aphone towers, extending from the
frontier to Petrograd, via Warsaw,
of over 1,200 miles, and employing
operators was erected at great ex-
.
Cologne and Coblenz, was estab-
32, at a cost of 170,000 thalers. In
ere was a semaphore line from Paris,
475 miles apart, and requiring 120

transmission of signals by semaphore
as necessarily slow (about one signal
!); inasmuch as each signal was veri-
ceiving station before another
itted. The time taken in transmit-
letter from Paris to Toulouse
over, comparatively speedy, namely, 10
ites.

tore signaling is still usefully em-
some countries for communicating
to shore, between coast-guard sta-
classes, etc. One plan of this

h as the semaphore system, were,
in quite extensive use, electricity
utilized experimentally long prior-
t for purposes of telegraphy but
in this direction was slow and the
with which its commercial utility
ere evidenced is evidenced by the es-
tablishment of semaphore stations
ed, long after the possibility of
electric telegraphy had been more or less
clearly indicated.

In 1774, Lesage of Geneva constructed an
electric telegraph system which employed in
its operation 24 line wires, one for each letter
of the alphabet. At the terminal of each wire
pitch balls were suitably suspended, and, taking
advantage of the well-known repellant effect
that follows the similar electrification of such
light substances, Lesage, by the use of fric-
tional electricity applied to the wires, trans-
mitted intelligible signals over them. In 1815
Francis Ronalds of England improved on this
arrangement. A revolving dial, operated by
clock-work, was employed at each end of a
wire. The dials rotated synchronously. A
notch was cut in each dial, behind which the
letters of the alphabet were placed in a circle,
so that as the dial revolved the letter at a
time was seen through the notch. Pitch balls
were electrically connected at each end of the
wire. At a given signal the dials were set in
rotation and as the notch arrived a particular
letter the pitch balls were actuated electrically.
The letter was noted and in that way messages
were transmitted. In 1774 Volta had dis-
covered that electricity could be generated by
means of the "voltaic" battery and, availing of
the current from such a battery efforts were
made, with more or less success, between the
years 1806 and 1830, to utilize the electrolytic
property of an electric current to decompose
chemical solutions at the distant end of a wire
to indicate telegraph signals. These experi-
ments were the precursors of others more suc-
cessful in the line of electrochemical telegraph
systems of later years, and to which further
reference will be made herein.

Needle Telegraph Systems.—Availing
of Oersted's discovery that a pivoted mag-
netic needle is deflected from its normal position,
parallel to a wire, when an electric current
passes in that wire needle telegraph systems
came into existence and were extensively
employed in Europe at one time and are yet in
use there. For this purpose a magnetic needle
is pivoted in the centre of a coil of wire, and
a pointer suitably attached to the needle, swings
in front of a dial. The needle and pointer can be
deflected by either hand or by changing the
direction of the current through the coil.

Certain deflections of the needle to the right or left,
combinations of deflections to the right and left
represent the letters of the alphabet, and these
deflections are produced by sending over the
wire current pulsations in positive or negative
direction, or alterations of both, as required by the
letter to be transmitted. For instance, if the Morse
alphabet were used, a motion to the right would
represent a dot; one to the left a dash. The
alterations of polarity are transmitted by a
"drop-handle" or a "tapper." The tapper is
similar to the double-sending key used in
submarine telegraphy. (See Fig. 15.) A needle
system employing two needles has also been
used. This required two wires, but gives a higher
rate of speed—about 15 to 20 words per minute.
The operator reads incoming signals by observ-
ing the movements of the needle or needles.

Bright's Bell.—A modification of the
needle telegraph is that known as "Bright's Bell,
which in which the bells of different tone are struck
by a hammer, one tone representing, for instance, a dot; the other, a dash. In other instances, the needle of the needle system is caused to strike metal tubes of different tones, one tone indicating a deflection in one direction, the other tone a deflection in the opposite direction. These have been termed acoustic telegraphs.

Electric Chemical Telegraphs.—See Automatic Telegraph Systems in this article.

Morse Electro-Magnetic Telegraph.—In 1824 Sturgeon of England discovered that when a current of electricity is caused to flow in an insulated coil of wire, surrounding a bar of soft iron (that is, well-annealed iron), the bar takes on magnetic properties, and when the current ceases to flow in the coil the iron at once loses its magnetism. Employing these electromagnetic phenomena, Morse, in 1837, invented the telegraph system which bears his name, and which to-day is in extensive use in one form or another in every part of the world. It was then known that when a piece of soft iron is placed near a magnet there is a mutual magnetic attraction which tends to draw them together. This fact is also availed of in the Morse telegraph system as will be shown in the case of the Morse relay and sounder.

To obtain the flow of current in the coil of wire required to magnetize the iron bar, the circuit must be complete, and a source of electromotive force must be provided.

An electric circuit may be represented, as in Fig. 1, by a line or wire, W; battery, B, the thin and thick lines of which in the figure conventionally represent the positive and negative plates or elements of a primary chemical battery. The source of electromotive force in telegraphy for many years in this country was the "bluesine" or "gravity" battery, the elements of which are zinc and copper in a solution of sulphate of copper in a glass jar. These cells are arranged in series: two or three for local circuits and from 25 to 350 for main line batteries. Of recent years these batteries and the bichromate primary batteries employed in Europe, have given way largely to storage batteries and dynamo machines as a source of electromotive force.

When dynamos are employed they are in some cases designed to develop about 70 volts each. Several of these machines are connected in series so that by tapping the machines at different points an electromotive force of 70, 140, 210 volts, etc., may be obtained. In other cases dynamos developing 70, 140, 300 volts, respectively, are employed. Two sets of such machines are provided, one set to furnish positive polarity, the other negative polarity, as much as is essential in the practice of telegraphy to utilize currents of opposite direction or polarity; instances of which will be noted in connection with the descriptions of quadruplex telegraphy in this article.

Reverting to Fig. 1, G is a galvanometer; an instrument to indicate the presence of electric current in a circuit, and which is connected on the principle of the iron needle of needle telegraph systems already mentioned. The direction of the current when the circuit is assumed to be from the positive pole of the battery B to the galvanometer G and back to the negative pole of the battery B; the key K affords a ready means of "breaking" and "closing," or of "making" and "holding" the circuit. When the key is closed, or the circuit is complete and current flows, the key is "open" or up, the circuit is broken, and no current flows. There is no difference between the ordinary telegraph circuit without instrucional means for completing the circuit from end to end.

In the Morse telegraph system, current is transmitted electronically from one station to another by the opening and closing of the circuit, or, by means of the short and long intervals, which actuate the Morse relay and sounder and register the sound of the Morse alphabet.

In Fig. 3 is shown theoretically the arrangement of apparatus of a Morse telegraph circuit at two terminal stations, X, Y. S is the battery; K is the Morse key. S is a core or bar, arranged in the shape of a shoe, around which a coil of fine wire is wound. A is a small piece of iron, the "armature," which is mounted pivoted lever r. A retractile spring e draws the armature from the electromagnet W, and when the latter is demagnetized the lever is released by the front one of which is a key that acts as a key for a local circuit. C are included small battery B, the sounder s. The relay R consists of the iron core, S, the coil of wire, and lever r. It also has devices for...
TELEGRAPHY

The armature relative to the ends, and screw posts for facilitating connections of the wires leading into and out of the instrument. (See Fig. 5).

In using the sounder in telegraphy is to obtain louder sound than that produced by the Morse relay. The relay developed in a given electro-magnet, relay or sounder, increases with the square of the currents, also with the number of turns of wire in the coils, within certain limits, up to the point of magnetism of the iron, the resulting magnetism proportioned to the product of the strength in amperes by the number of turns, or turns, of wire; which product the "ampere turns." Saturation is seldom or never reached in the magnet telegraph. Again, with a given force the current strength is proportional to the resistance of the wire as the resistance of a wire of given number of turns of a given gauge of wire, the weaker will be the current. That to produce the clear, loud, click sound of the Morse sounder, about .25 amperes, while a main line relay will only require about .01 amperes. To operate a sounder placed in a line of 1,200 ohms resistance would require a motive force of about 300 volts. It is more economical and in other ways employ a lower electro-motive force. The volt in this case, and a relay having as of finer wire than the sounder (30 B & S gauge) and a light armature designed to produce a large volume of sound by means of its armature a "logical" battery is then caused to sound as indicated in Fig. 1.

A sounder is constructed on the same principle as the relay, but the wire with which it is larger, about No. 24 B & S gauge, mature and lever are heavier. Since the relay controls the local circuit, sounder it follows that as the main end and opened, thereby closing and opening the relay, the local circuit will be opened and closed, by which actions the magnet of the sounder will be corded alternately magnetized and demagnetized, and the armature lever will be attracted by the magnetism and withdrawn by the tension of the armature spring. The motions of the armature produce the long sounds which are translated into letters habed by an expert operator. When register or ink recorder is used in the sounder these dots and dashes are recorded or printed on strips of paper. The message may then be transmitted to any one familiar with the dot and dash language.

Plainly many more relays may be used in the main circuit than are shown in the diagram, and 40 relays in one Morse telegraph with two main batteries, one at each end. When any one of the keys of a telegraph circuit is open none of the keys can close the circuit, and one key is operated at a time. The wire will be operated concurrently, of the opening and closing of the key. Any attempt to operate two keys at once on this circuit results in a clashing of signals. Such circuits are termed "single" or "simplex," inasmuch as but one message at a time can be sent over them. This fact distinguishes simplex from multiple circuits over which two or more messages can be transmitted simultaneously, instances of which will be given herein.

The arrangement of Morse circuits just described is termed the "closed circuit" method of operation, from the fact that the circuit is normally closed with current on the line. In Europe the Morse circuits have generally been operated on what is termed the "open circuit" plan, which consists in so arranging the apparatus that the battery shall only be placed to the line when a message is to be transmitted; at other times the battery is disconnected from the line. For this purpose a key with front and back contacts is used, similar to K in Fig. 12; battery being placed as there shown, and the receiving instrument being placed in the circuit of the back contact at s in that figure. In the open circuit method battery is necessary at every station.

Telegraph Alphabets.—The American Morse code or alphabet which is in general use on overland Morse telegraph lines in the United States and Canada is composed of dots and dashes and of combinations of dots, dashes and spaces. Letters made up partly of spaces are termed "spaced" letters. The letters C and R are instances of spaced letters. (See illustration below). Dots, dashes and spaces are formed by the length of time during which the key or other transmitting instrument may be held closed or open; the

</table>
and is insulated therefrom by a hard-bushing. On its top there is a cone cap, termed the anvil, carrying a contact point. At a point under side, directly above the lever, a lever 1 is provided with a platinum tip termed the hammer. A curved strip on 9, the "circuit closer," is pivoted on 6. When the circuit closer is lifted, the strip projects from the cap 1, a circuit, regardless of the opening between anvil and the hammer. The lever 1 circuit closer 9 are supplied with finger tips, or knobs, by which it is handled freely without danger of spring adjustable by a set screw 7, lifts the lever 1 from the anvil. The operator is about to "send," the circuit must be first pushed out from 7 so the lever when operated may open to the circuit; for it will be seen that when the lever is brought into contact with the circuit is closed at that point. It is employed at all important contacts of its durability and freedom from oxide due to the sparking which usually occurs in electric circuits are broken. The magne operated Morse keys employed in Great Britain and Europe are practically similar to shown here, but they are larger and heavier. Morse Telegraph Relay. The electromagnets which Morse first employed in telegraph weighed over 300 pounds. In 1844, however, the weight of this instrument had been reduced to 185 pounds. Within 15 years that time many improvements had been in the instrument and it then was little more than the modern (typified in Fig. 5), about three years late as 1867 relays were wound to the present standard resistance of 150 ohms. In the case of are termed "low resistance" relays the are wound to 37.5 ohms. These relays utilized in a number of instances they are employed on one circuit, the way telegraph lines and the total red resistance brought about by their are used to effect a very beneficial result in the circuits in wet and dry. The obvious explanation of this since the electric current seeks the lower the more wire circuit the less will be the current to escape by the "leaks" where foliage, trees, etc., touch the wire.

One is designed to give resonant effects. used on primary battery circuits these 8s are wound to 4 ohms; when em- on dynamo circuits they are often to 20 and 40 ohms.

egraph Transmitters.—With the obj ect ins a simple and speedier method of ting the characters of his alphabet he manually operated key method, devised several mechanical arrange- One of these consisted of a plate of or wood on the surface of which aced in a vertical row short and long if metal, corresponding to the letters alphabet. These strips were all me r connected under the plate by a wire ed to the battery, relay and ground. e wire was connected by an insulated metal strip, or. This strips was held sand of the operator and in transmit message he would run the point of the over the metal strips representing the

given letters, thereby closing and opening the circuit, in a manner corresponding to the manual transmission of the letter. Another somewhat similar device, also due to Morse, consisted of a metal cylinder on the surface of which the characters of the Morse alphabet were arranged in a practically similar way. A keyboard was arranged over this cylinder and the depression of a key brought a metal brush into contact with the cylinder. At the same time the cylinder was caused to make a partial revolution. The characters on the cylinder being connected to the line, and the brush to the earth, the foregoing described actions resulted in the transmission of Morse characters. These transmitters did not go into wide use at that time, but within the past four or five years a keyboard transmitter, termed the “Yetman” transmitter, which is a much improved form of the Morse cylinder transmitter, has been largely adopted by telegraph operators in this country. The employment by operators of the typewriters as a means of transcribing received messages, which gave the receiving operator an advantage over the sending operator who could only send from 30 to 40 words per minute at best speed. By means of the keyboard transmitter a speed of transmission approaching the speed of transcrip- tion by the typewriter is obtained. This use of the typewriter was accompanied by a new arrangement of the sounder, which is now placed in a box, or resonator, mounted on an adjustable rod that brings the sounder in close proximity to the ear of the operator.

Lightning Arresters.—Lightning discharges tend to follow telegraph wires into cables across rivers, and into the telegraph offices, causing damage to the cables and instruments. Damage is sometimes caused also by the contact of telegraph wires with electric light and power wires. To prevent as far as possible damage from these causes, lightning arresters and fuses are placed at points just outside of cables and at points where the wires enter offices. A combination lightning arrester and

FIG. 7.—Lightning Arrester and Fuse Wire.

fuse wire is shown in Fig. 7. F is a small fuse wire carried on a strip of mica m which is tipped with metal at each end, and held by metal clips n, n'. C represents two small blocks of carbon separated by a thin layer of mica, and held in position by metal tension springs n, n. The left-hand block is connected to ground at the post G; the right-hand block is connected to the screw A from which a wire leads to the apparatus. The line wire is connected to the screw L. A strong current passing through the fine wire F will fuse it; a lightning discharge will jump to ground by way of the carbon blocks; in either case protecting the cable or instrument.

Automatic Telegraph Repeaters.—The function of a Morse automatic repeater is to take, as it were, the message from one wire
and "relay" it to another wire without the intervention of an operator. Some of the reasons that render repeaters necessary are, first, that the resistance of the wire increases directly with its length, which tends to a diminution of current strength; second, the escape of current from the line wire at points where it makes contact with trees is greater on a wire of high resistance than one of low resistance (see Relays); third, the speed of signaling decreases as the electrostatic capacity is increased and this capacity increases with the length of the wire. Hence it is found desirable in practice to limit the direct length of a telegraph circuit to a maximum of about 500 miles in this country.

The apparatus and circuits of an automatic telegraph repeater at an intermediate station are outlined theoretically in Fig. 8. This is known as the "Toye" repeater, which was at one time much in use, and is chosen for illustration because of its comparative simplicity. It may be noticed that relay $R$ controls the "continuity preserving" transmitter $T'$ by means of its armature lever $m$, and local battery $b$; while relay $R'$ controls $T'$ by means of lever $m'$ and battery $b'$. Also that transmitter $T$ controls the western main circuit at $x$; while $T'$ controls the eastern circuit at $x'$. In practice $T$ is the "opposite" transmitter to relay $R$, and $T'$ is the "opposite" transmitter to $R'$. In the operation of an automatic repeater the desideratum is automatically to keep the "opposite" transmitter passive while its circuit is being repeated into, in shop phrase. The operation of the Toye repeater is as follows: Assume that the East is sending to the West. When the eastern operator opens his key, thereby opening the eastern circuit, relay $R$ opens, as in the figure. This opens transmitter $T$, and in consequence the western circuit is opened at $x$. At the instant, however, that the western circuit is opened at $x$, the circuit which includes the relay $R'$ and main battery $M'$ is closed via the lever of $T$, through a resistance $Rh$ equal to that of the eastern circuit. As this transposition or substitution of circuits maintains the current passing through relay $R'$ at the same strength as before the change of circuits was made that relay, and, consequently, the transmitter $T'$ remains closed. In this way the "opposite" transmitter is automatically kept passive. When the eastern operator again closes his key, relay $R$, and in turn $T$, are likewise closed, resulting in the closing of the western circuit at $x$. When the West sends to the East the description is reversed.

Among the other automatic repeaters in use may be mentioned, the Neilton, the Weiny, the Mayer-Atkinson, the Ghegan and the Var.

Automatic Telegraph Systems. Automatic telegraphy consists of apparatus whereby Morse characters are sent at a rate of speed ranging from 2,000 to 3,000 words per minute. As speed of hand transmission of Morse characters is from, say, 15 to 40 words per minute it is obvious that by the use of a telegraph system many more messages can be transmitted over one wire in the same time than by the manual method; and the cost of construction and maintenance of the wires is a large portion of the expense of the telegraph equipment. If every advantage is equally weighed, the advantage would be on the side of the automatic systems. But, unfortunately, everything else is not the same. In the first place, every automatic Morse system has to be prepared for transmission by the type of the machine, and every message has to be transcribed manually before it is delivered to the addressee. This involves a larger labor in the making of operators than is necessary in the manual transmission of messages. In the second place, the number of messages manually transmitted is also greater delay in the handling of messages by reason of the address of the addressee. There is for the same reason less liability to errors by automatic transmission than by manual transmission. Nevertheless, certain automatic systems, like the Wheatstone, for instance, are found of much utility.

There are two general types of telegraph systems, namely, telegraphic and ink recording, or electromechanical systems. The former relates to recording the electrochemical action produced by the recorder, the latter to recording the sensory impulses. The chemical telegraph is usually prepared in the form of a strip of paper, hole corresponding to the character of the Morse alphabet, is then drawn over a metal roller rests a steel needle or brush; the metal roller being made a part of the circuit on which there is a primary battery or an electrochemical source. A strip of paper is drawn along the needle, which drops into the holes in the paper and contacts with the roller and completes the circuit. In this way current pulsations in duration to dots and dashes are made through the wire. At the receiving station, practically the same arrangement is made, but the perforated paper is not used. Instead, a strip of paper that has been coated with chemical solution is drawn over the roller.
TELEGRAPHY 385

Wheatstone Automatic Telegraph — This recording system. Its apparatus con-
forming machine by which mes-
prepared for transmission; a trans-
mitter utilizes the perforated paper to
messages thus prepared, and a re-
d, being actuated by the electrical
set up by the transmitter, records
ke, on stiff paper tape, as dots and
perforator consists of small hol-
ers with keen edges, driven by the pressure
which the paper to be perforated is
pass. Three discs, connected with
orders and representing the dot, dash
are depressed by the stroke of a
the hands of an operator, with
that holes of a certain order are
the paper. Thus when the dot
pressed, three vertical holes are cut;
dash disc is depressed two vertical
horizontal holes are cut, and the then
disc is depressed one central hole is
ly as shown at the left of Fig. 9.
mitter in its operation takes the
he operator's hand and formulates
shakes with an accuracy superior to
peed 10 to 15 times greater than the
operator can attain. That por-
an transmitting signals is outlined in
L L are vertical rods attached at
tips to crank-levers A' A, respec-
tively, means of adjusting screws F, F, L'
the left of L a distance equal to the
ween any two horizontal central
ie paper. The crank-levers are pro-
ed D of M; the line wire to the upper end P';
D and P' being insulated from one another.
The lever M is really a pole-changing key
and the rods and levers simply displace
the operator's fingers, causing that key to reverse
the poles of the battery. In the present po-
ition of M in the figure the negative pole of
the battery is placed to the line. The per-
forated paper is shown by a single line and
the rod L has passed through a hole in
the paper. A revolving star-wheel H' is made
with the central rows of holes in the paper
and draws it along at a uniform rate of speed.
Assuming there is another hole in the paper
immediately opposite that one through which
L has just passed, when the lever L' moves
upward it will pass through that hole, the
paper having been moved forward by the
star-wheel just enough to bring the hole op-
posite L'. At the same time, by the down-
ward motion of L the collet C has been
withdrawn, giving collet C' on H' free scope to
push D against its right contact, 4, and P'
against the contact 1 which it will be seen
reverses the polarity of the battery to line.
If a succession of dot holes were punched
on the paper, a succession of short, direct
and negative currents would pass over the
line. When, however, a set of diagonal holes,
as at Y in Fig. 9, is punched on the paper,
the result is different, for at the first upward
movement of L it will pass through the hole,
pushing end P' of M to the right, but at the
following upward movement of L' it meets the
paper at a point opposite the hole through
which L had just passed and its further up-
ward motion is arrested. Hence M is not
pushed over and the battery is not reversed.
At the next upward movement of L its motion
is similarly arrested and the polarity of
the battery is still unchanged, until at the next
upward movement of L' it comes opposite and
passes through the hole M, causing the collet
C' to push D against contact 4, thereby revers-
ing the poles of the battery to line. This delay
in the reversal of the battery is sufficient to
make an appreciable difference in the length of the
signal recorded, and constitutes a dash.
The effect of these different actions is that,
depending on the position of the perforations
in the paper strip, dots and dashes are trans-
mitted by the pole-changer M.

The Wheatstone automatic receiver, or ink
recorder, consists of a polarized relay (see
Polar Duplex in this article), the armature
lever of which is extended at a right angle at
its upper end, and this extension at certain
times is caused to impinge against a light rod
pivoted at one end. On the end of this rod
is a small circular disc, the lower portion
of whose periphery is immersed in an ink well;
an upper portion of its periphery is placed
very near the stiff paper tape previously
mentioned. The axle of this disc is given a slight
tension away from the paper. When, however,
a current of positive polarity, designed to re-
cord a dot or dash on the paper, actuates the
polarized relay, its extended armature lever
presses against the axle of the disc causing it
to deposit a mark on the moving paper tape.
A negative current causes the withdrawal of
the disc from the paper. The positive current
in this system is termed a "marking" current;
the negative current a "spacing" current, when
TELEGRAPHY

It is operated by the "double current" or reversal of polarity method; to which further reference will be made in connection with Duplex Telegraphy, also in this article. The circular disc is kept in rotation by a simple clockwork mechanism and thus constantly renewal its supply of ink. The paper strip is drawn forward at a desired rate by rollers operated by mechanism within the box.

The Wheatstone automatic telegraph may be worked duplex by using a differentially wound relay and the other necessary apparatus of a duplex system. When worked as a duplex it gives a wire of moderate length, in which there are no very long submarine or underground cables, a capacity of from 200 to 350 words in each direction. On a 1,000-mile duplex circuit, such as from New York to Chicago, with one repeater station at Buffalo, a speed of about 125 words per minute in each direction is now obtainable.

Writing Telegraph Systems.—Writing or automatic telegraph systems transmit and record facsimiles of letters or characters while they are being formed by the stylus or pen in the hand of the operator. The first to produce a writing telegraph system was probably Mr. A. E. Cowper, of England, who employed in the operation of his system the principle of the parallelogram of forces, whereby by compounding the movements of a point in two directions, the one at an angle to the other, the actual movement of the point is the resultant of the two movements. The Telautograph (g.v.) also operates on this principle. In the Cowper system the receiving pen depends for its movements upon variations of the magnetism of two electromagnets placed at right angles to one another, which variations produce changes in their magnetic fields, to which changes an armature carrying the receiving pen is free to respond. The magnets are placed in separate circuits. The variations in the magnetic strength of the magnets are caused by variations of the current strength in their circuits, which variations are brought about by means of a pencil which when moved by the operator in the act of writing is caused to switch resistance coils in and out of the respective circuits.

Duplex Telegraphy.—This consists in the sending of two messages over one wire, in opposite directions at the same time. Since on an ordinary Morse telegraph circuit it is not possible to send more than one message at a time over a wire, it is essential, in order to make duplex telegraphy possible, that the signals transmitted from the sending station shall not interfere with the signals to be received at that station. The receiving instruments must, therefore, be so constructed or placed that while ready to respond to all signals from the distant station they shall not respond to signals from the near or home station. These requirements are met in two ways in practice: one method being known as the "differential," the other as the "bridge" method.

The differential plan is used almost exclusively on land line duplex telegraphy; the bridge plan is used in submarine cable telegraphy. The "differential" plan avails of the fact that if a soft iron bar or core, B

wires 1 and 2 remain as before, but the bar H is now connected between them as wound with but one coil. a', b' are coil resistance, termed the arms of the i (Wheatstone bridge). Assuming the n of wires a', b' and wires 1 and 2 to be the electric pressure due to battery b, terminals of the bridge wire, will be opposite, and hence no current will the bridge wire.

There are two systems of duplex telegraphy in use in this country and in England, namely, the "Stearns" duplex and the "Wheatstone" duplex, and these combined comprise the "Quadraplex," described later.

The Stearns Duplex.—The Stearns duplex is operated by increment and decrement of current on the line, virtually as in a Morse system is operated, namely, bringing a current over the line to act as a distant relay, which attracts its armature by removing the current from the near station. The Stearns duplex may also be considered as a land line duplex, except that instead of a single submarine cable, there is a pair of cables. The "differential" plan avails of the fact that if a soft iron bar or core, B

the iron bar, and as each current up opposite magnetic poles in the coil the current will neutralize the other and no effect will be produced in the wire 1 at its distant or right-hand end, a amount of current will flow in coil 1 and in consequence the core magnetized to a degree depending on the strength of currents on the respective coils; hence the term "differential" and a relay wound in this way is a differential relay. The theory of the "differential" plan is outlined in Fig. 11. The battery,
The stearns duplex is shown in Fig. 12, represents the apparatus at two stations $A$ and $B$. The relays $M, M'$ are wound on coils in opposite directions around $D$; one of the coils of each relay being $l$ to the main line and the other to a resistance coils, $R, R', K$ and $K'$ for the purpose of making the circuit complete and to act as keying keys. When key $K$ is closed, positive electromotive force is applied to the key $K'$ and closed so as to make a negative force to the line. When the line wire is placed to $B$, since the battery current will divide the two coils of the relay in the resistance of the circuits to each coil, a means must be provided to make those circuits of equal resistance in order that unequal currents will flow in the resistances and the relays will be operated. It is the function of the rheostats $R$ to provide a resistance that of the main line and the main resistance, of the distant relay, so that there will be a balance. In the figure, key $K$ and $K'$ open, a current flows in the line from $A$ to $B$. As currents are flowing in opposite directions through the core of relay $M$, its armature is attracted. On the other hand, as there is a path for the current from $B$ to earth, back contact of key $K'$, no current will flow through coil 2 of relay $M'$. Hence, the core of $M'$ is magnetized.

Fig. 12.—Theory of Stearns Duplex.

It acts its armature $a'$ as shown. If $K'$ should be closed this would add negative polarity to the main line making 200 volts on the main line, would place only 100 volts to the artificial coil at $B$. Hence double the amount it flows in the line coils 1 of each of the other coil, the line flows through the artificial line coil. Thus the armature $a'$ of $M'$ is now and armature $a$ of $M$ continues to act as current to $B$.

Polar Duplex.—This system also employs wound relay, transmitting main and artificial lines similar to the Stearns duplex and for the same but the type of transmitting keys and different in the two systems. Relay employed in this system is termed the relay $E, E'$, Fig. 13) and is based upon the principle, that unlike magnetic poles attract each other and that the pole of one bar in contact, say its north pole $N$, be so pivoted that it will move freely toward the south pole of an electromagnet $E$; it will follow that by changing the direction of the current flowing in the coils of the electromagnet, the permanent magnet $a$, which will oscillate between the poles, will be caused to follow the changes of polarity in the electromagnet. If the permanent magnet $a$, which is virtually the armature of a polarized relay, be given control of a local circuit containing a sounder $D$ and battery $b$, it may be caused to record signals in a manner practically similar to that in which the Stearns' relay records them. It is only necessary to provide a pole-changing key $F$ to reverse the direction of the current flowing in the line, to bring about this result. Fig. 13 represents in theory the circuit and apparatus of a differential polar duplex; the apparatus and arrangement of circuits at the terminal stations $A$ and $B$ being indicated. When the pole-changer $F$ is closed, the current flows to $B$. As current flows to the line and the direction of the current is as indicated by the arrows. When the key $F'$ at $B$ is closed, a negative pole of a battery is placed to the line. In these positions of the keys the direction of the currents in the main and artificial lines is as shown by the arrows, and the relays at both ends of the line are recording a signal, the sounders being attracted. This is due to the fact that an excess of current is flowing in the line coils at $B$ in a direction to produce magnetic poles in the cores of the relays as marked. If now, for instance, the key $F'$ at $B$ should be opened the effect would be to place a positive pole of the battery to the line. The effect of this is that each end of the main line is placed at equal and like potentials, and hence no current flows over the main line or in the main line coils of the relay. A positive current from the battery at $A$ with a strength of say 1 will still flow through artificial line coil at $A$, but in a direction which will reverse the previous polarity of the core; consequently the armature of the relay is attracted to the left side and the local circuit of sounder $D$ is opened. An examination of the conditions will show in every case that when the pole-changer at either end is opened or closed, the local circuits controlled by the armature of the distant relays will also be "opened" or "closed." From which it follows that dots and dashes may be transmitted from both ends of the line simultaneously by a proper manipulation of the pole changers.

The instrument $C$ shown at $A$ and $B$ is an electrical condenser. It performs a very
useful function in duplex and quadruplex telegraphy as follows. The artificial line coils $R K$ which are used to "balance" with are usually composed of spoons of fine German silver wire, wound double, or non-inductively, so that they may not possess any perceptible magnetic effect or inductance. These coils have no static capacity. The main line it is known does possess static capacity. Hence at the moment of charging and discharging the line there is a momentary inrush and outrush of current into and from the line greater than that due to the ohmic resistance of the line. This would produce a momentary inequality in the current in the coils of the relays unless equal capacity were given to the artificial line. This is done by adding the condensers $C C'$ to the artificial line. These condensers are adjustable and by means of metal plugs more or less capacity may be added until a static balance is obtained. The rheostats are also adjustable in order that the resistance balance may be readily obtained.

The Quadruplex (Edison).—The Stearns duplex depends for its operation upon the increase or decrease of the strength of current on the line, regardless of the direction (polarity) of the current, whilst the polar duplex depends upon changes in the direction of the current regardless of current strength. In the operation of the Edison quadruplex system both of these principles are combined on one wire; the instruments used being the transmitting key (transmitter) and Morse relay (the neutral relay) of the Stearns duplex, and the pole-changer and polarized relay of the polar duplex.

The relays are wound differentially for the purpose stated previously and rheostats, condensers, etc., are employed, as in the duplex systems described. In the Stearns duplex, when the transmitter is open there is no electromotive force to the line, the wire in that case being placed directly to ground. Since the polar duplex depends for its operation upon the reversal of polarity, provision is made for this requirement in the quadruplex by so arranging the connections of the transmitter $K$ that when the latter is "open" a small portion, 1, of battery $B$ is left in the circuit to be opposed to the pole-changer $P C$. When $K$ is closed, the full battery $B$ is reversed by the pole-changer. On the other hand, when the small portion 1 of battery $B$ is to the line, and only a weak current is traversing the line, the adjustment of the retractile spring is such that the armature $A$ is withdrawn from the core; while, when the key $K$ is closed, and the full strength of battery passes to line, the armature is attracted. Both stations are equipped. Thus an operator may read, t and the consequent increase and decrease the current strength will operate the neutral relay $N$. But the operation of a will not practically affect the distant relay $P$ inasmuch as the armature is caused to change the direction of current on the line. On the other hand the pole-changer $P C$ will operate the distant neutral relay. Thus two signals may be sent in opposite directions at once over a quadruplex circuit; this system, therefore, giving the equivalent of four wires. The three wires thus gained are "phantom" wires.

Many details of apparatus require practice are, for lack of space, omitted, but complete details of these systems are given in the author's "American Telegraphy" Encyclopedia of the Telegraph; from work a number of the diagrams used in this article are reproduced with the consent of the publishers.

Submarine Cable Telegraphy.—The strength of signaling through an electrical circuit is inversely proportional to the product of the electrostatic capacity and resistance of a conductor line directly with its length. The capacity varies with the material comprising the conducting medium (see ELECTRIC CONDUCTORS). The high electrostatic capacity and the length of submarine cables conduct to the danger of signaling. When a long cable is connected with a source of electromotive force the discharge is communicated to the distant end almost immediately, but the amount of charge at arriving is extremely small and the current current rises slowly thereafter to its maximum. The discharge is approximately as great as the charge. Hence a desideratum in submarine telegraphy is a receiving instrument that will respond to a very feeble current. A weaker the current required the shorter the time of charging and discharging the and the more rapid will be the rate of signaling. The first successful receiving instrument devised for this work was a mirror galvanometer (see ELECTRIC MIRRORS). The light from a lamp is thrown to a mirror and the light is reflected back to a screen. The mirror is carried on a system including several very small needles, which are in the centre of a fine wire, the coil being in the circuit. Minute pulsations of current or needles to be deflected to the right or left, according to the direction of the currents, causes the spot of light on the screen to be focused to the right or left. A deflection right constitutes a dash, one to the left. The direction of the deflections is reversed by means of a special form of key (K), Fig., a positive and negative currents may be transmitted. The mirror receiver gives no indication of the message, the signals being written by the operator as they are received.

A later invention, the Siphon recorder, due to Sir Wm. Thomson (Lord Kelvin) comes to notice this objection. This instrument.
Fig. 15, consists of a coil of fine copper which is suspended between the poles of a powerful magnet, \( M \), in such a manner that, when a current passes through the coil, it sets itself at right angles to the lines of the magnetic field. When no current is flowing in the coil, two small weights, placed at the lower end of the coil, in the plane of the magnetic lines of the magnet, A, make it possible for the coil to remain stationary. A siphon, \( C \), consisting of a small glass tube is attached to the coil wire. The lower and bent end of the siphon is placed directly over the centre, or eye, of a paper ribbon, \( P \). The pole-changing key, \( K \), sets up momentary elastic tension of the diaphragm, and produces the diaphragm of the telephone, and the sound produced is transmitted into the telephone. The key, \( K \), is made of a light, flexible material, such as rubber, and is moved by a light spring, \( S \), which is attached to the key and maintains it in a neutral position. When the key is moved, the spring is compressed, and the diaphragm is displaced, producing the sound.

Simultaneous Telegraphy and Telephony.

This is sometimes erroneously termed "composite telegraphy." The art relates to telegraphing and telephoning over one wire at the same time.

When a telephone receiver is inserted in an ordinary telegraph circuit, the operation of the Morse keys deflects the diaphragm abruptly and produces loud noises in the telephone, which render the reception of speech nearly impossible. Van Rysselberghe, of Belgium, discovered that if the rise and fall of the telegraph currents were made gradual, no disturbing sounds would be heard in the telephone. To bring about this result he introduced into the telegraph circuit a combination of electromagnets and condensers, which by retarding the rise and prolonging the fall of the telegraph currents merely inhibit the diaphragm of the telephone, but do not produce any sound thereby. When this result is obtained the telephone currents may then be superposed upon the telegraph currents without impairing the efficiency of the telegraph signals. Simultaneous telegraphy and telephony is now in successful use in the United States on a large scale; two telegraph circuits are being operated as one telephone metallic (two wire) circuit, on circuits up to 400 miles in length.

Synchronous Multiplex Telegraphy.

It is known that 500 pulsations of electricity per second can be transmitted on an overhead wire of moderate length. A telegraph operator at his best speed is not capable of transmitting more than an average of 10 dots per second. Hence it was thought that if means could be devised whereby a number of operators should consecutively be given exclusive control of a wire for brief intervals of time the same wire might be utilized to transmit four, six or more messages at practically the same time. In order that this might be done satisfactorily it was evident that the corresponding transmitting and receiving instruments at the near and distant stations should be placed in connection with the wire at identical instants. This entailed the construction of devices for obtaining exact synchronism; hence the name of the system.

The apparatus for obtaining synchronism and for apportioning the wire among a number of operators consists of a revolving wheel at each end of the telegraph line, the wheels revolving as nearly as possible at a uniform rate. Each wheel is driven by an electric motor whose motion is controlled by a vibrating reed at each station, which reeds are attuned to the same rate of vibration, as closely as possible. This wheel is supported on a vertical shaft. Below it is a stationary circular disc made up chiefly of a large number of metal
segments (84) radiating from near the centre of the disc, and insulated from one another by suitable material. The shaft supporting the wheel passes through the centre of the disc. The shaft carries by a suitable projection a brush or trailer, which, as the wheel revolves, is swept over the segments in rapid succession. As the trailer makes three revolutions per second, it passes over each segment three times per second. If it is desired to transmit six messages at once, 72 segments are set apart for the purpose, and each of six desks at each end of the wire are allotted 12 segments. That is, starting from any given point on the disc, the first segment will be given to desk No. 1; the second segment to desk No. 2, and so on to the sixth segment, where two segments are skipped, being reserved for synchronizing purposes. A second series of six segments is then connected to desks Nos. 1, 2, 3, and so on around the disc. The line wire is connected to the shaft or trailer of the revolving wheel at each station, and, consequently, as the trailer makes three revolutions per second, the disc is in contact with the line, and with its corresponding desk at the distant station, 36 times per second. As an operator cannot make a dot in less than the one-twelfth of a second it follows that in that time the trailer will have given him contact with the line twice. Hence each one of six operators may transmit messages as though he had entire control of the line. As each character received at any one desk is caused by a drum to make motions an arrangement of relays with a contact on the "lack-stop" is employed which delivers the signals virtually unbroken at the receiving end. Synchronization is maintained by means of the two segments referred to which send "correction" impulsus that retard or accelerate the speed of the wheel that carries the trailer.

Dial Telegraph.—Various known as dial, A, B, C, and pointer telegraph system; due to Breguet, Kramer, Frischen, Wheatstone and Siemens. The systems employ a dial carrying on an outer circle the letters of the alphabet and on an inner circle figures and punctuation marks. A pointer operated by suitable mechanism within a case moves like the minute hand of a clock around the dial in response to pulsations of electricity from a sending instrument. The sending instrument has a similar dial and is equipped with a key which is movable around the face of the dial. As the key is thus moved it opens or closes a circuit, or it causes the movement of a magnet before coils of wire within the case, that transmits pulsations of electricity over the line, which in turn actuate, by means of an electromagnet, a cam which moves the pointer as stated. The operator moves the transmitting key uniformly around the dial. As he does so the pointer on the receiving instrument moves a corresponding distance. When the key arrives at a desired letter the operator places his finger on the point opposite the letter on the dial and thus makes the key to the next desired letter, and so on, in this manner spelling out his message. This system is slow, but it possesses the advantage of requiring little movement of the operator. Hence, especially before the days of the telephone it was in favor as a means of communication between police fire headquarters, on railroads, etc. As where stated telegraphs of this order are in use in other countries.

Military and Naval Telegraph.—Telegraphy is quite extensively employed in army and navy of this and other o. The distance covered by any variations is about 25 miles. Signals are transmitted by reflections of the rays of the reflection and the duration of the reflections being correspond to dots and dashes of or any other preassumed code. One heliograph consists of a mirror in a socket and supported on the end of a tripod. The reflections are in the direction of the distant station signals are sent by interposing the hand screen before the mirror. When the not in a suitable position to admit of its reflection in a desired direction, two are employed, one facing the sun, which reflects the sun's rays upon the mirror facing distant station.

Flag-signaling, termed wig-wagging, flash signaling by lanterns and search, also by horns, whistles and sirens are employed by the various armies and navies 0. world. Also Morse telegraphy and wire telegraphy (q.v.). Torches at night take the place of the flag in signaling. In flag and signaling, as well as in heliography and signaling the Continental Morse alphabet is now used. Arbitrary characters of this system have been standardized in telegraph systems in which a deflection to the left is represented by the figure "1"; a deflection to the right by the figure "3." Thus A is represented by "3" in one such alphabet.

In wig-wagging or torch signaling the man faces exactly toward the distant staff is vertical in front of centre of b at height of waist. When the Morse is employed, a dot is represented by a of flag or torch and a dash by the left; the space by a "front" motion.

SEMIPHORE

Printing Telegraph, Stock T

Printing telegraphy relates to those systems in which telegrams are printed received on strips or sheets of paper. Gem speaking, printing telegraph systems of stock ticker type depend for their operation upon the synchronous rotation of a cylinder at a receiving station with a wheel at a sending station. If, for two wheels of equal size having peripheries type letters of the placed side by side and are caused to rotate at a constant synchronous rotation of two or such wheels or cyzitwheels, it is obvious that if it they start with a letter at a given point, each wheel will present a similar letter at the given time as long as the wheels rotate at equal speed. However, a difficult matter to obtain uniform synchronous rotation of two or such wheels or cyzitwheels, which are revolving at a high rate of speed, their movements are under control of master wheel or transmitter. On account of this, the control of electrical printing telegraphy, consists in the well-known "ticker" by type-wheels of the tickers in the various
TELEGRAPH

Under control of a transmitter which
s them in synchronism by a "step-by-
vement, so called. In certain other
telegraph systems, such as the Hughes,
used in Europe, the uniform rotation
transmitting and receiving wheels is
ed by a nearly synchronous rotation of
rs at each end of the circuit, and, in
by a "correcting" device applied to

Assuming that the wheel \( W \) sends out 32
electrical pulsations in one revolution these
pulsations will cause one revolution of the
type-wheel. Thus, if the transmitter be set
in motion with brush \( B \) resting on the seg-
ment that is in line with, say, the pin under
key \( A \); while the letter \( A \) on the type-wheel
is opposite the platen \( P \) on the end of the
lever of the press-magnet, it follows that for
every revolution, or part of a revolution, of
the cylinder just enough pulsations will be
transmitted to cause the type-wheel to pre-
sent a letter opposite the platen corresponding
to the key depressed. If the transmitter and

type-wheel do not start with corresponding
letters in the required position misprints fol-
low. This is obviated by having the appar-
atus to a "unison" point after a few re-
volutions of the cylinder. The speed of
rotation of this apparatus is about 120 re-
volutions per minute.

The apparatus shown prints letters only.
When figures are to be printed, a figure wheel
is placed on the shaft, side by side with the
letter wheel, and a "shifting" device is em-
ployed which shifts the letter or figure wheel
under the printing platen when a letter or
figure is to be printed. Usually two wires are
employed in the latter case, one to operate the
"shift" apparatus.

In printing telegraph systems of the kind
just mentioned, considerable loss of time en-
sues from the fact that frequently it is neces-
sary to rotate the type-wheel the greater part
of a revolution in order to print one letter. Thus,
if the letter \( A \) follows \( B \) in a given word, it
will require 31 pulsations of current to print \( A \),
assuming that there are 32 letters and punctu-
ation marks on the type-wheel. If \( R \) follows \( C \),
15 pulsations will be necessary. This conduces
to a low rate of speed, perhaps an average of
30 to 40 words per minute; the message being
printed on a paper strip.

Hughes' Printing Telegraph.—An under-
standing of the operation of this system may
be gathered in a general way from the im-
mediately preceding remarks. It is not, how-
ever, a step-by-step system, but depends for its
operation on the synchronus rotation of two
wheels, one at each end. When a key of the
keyboard is depressed at the sending station it
catches a pin on a rotating wheel, or chariot,
but does not stop the wheel. The pin so caught,
however, at that instant causes the transmission
of an electric current over the line. This
pulsation in turn instantly operates an elec-
 tromagnet at the receiving end which trips a
device that throws the paper strip against the
letter on a type-wheel which at that moment is
in the printing position, and, assuming the
transmitting and receiving apparatus to be in
synchronism, a letter corresponding to the key
depressed will be printed at the receiving
station. The synchronous rotation of the
wheels is obtained primarily by means of a
pendulum at each station which is adjusted and
arranged to ensure a proximate rate of rotation
TELEGRAPHY

to the respective wheels, but as the pendulums alone cannot be depended upon to maintain proper synchronism, a cam arrangement is provided which, every time a letter is printed, moves into a receptacle on the edge of the printing wheel and corrects the synchronism of the wheel, putting the wheel slightly forward or backward, as may be necessary. Pulsations of current are thus only transmitted over the line when a letter is being printed.

Buckingham Page Printer.—To avoid the loss of time due to the rotation of a single type-wheel with many characters the Buckingham printer (in one of its forms) employs four very small octagonal type-wheels mounted side by side on one shaft. On the periphery of each wheel eight letters and other characters are placed, 32 all in all. The shaft on which these type-wheels are mounted is so arranged that by an ingenious disposition of five electro-mechanically operated levers, it may be given both a lateral and a rotary motion such that any one of the 32 characters on the type-wheels may be placed before a given point for printing, by five pulsations of current. The selection and printing of any letter or punctuation mark are brought about by a cycle of six pulsations of current in all—that is, three alternations of polarity. These pulsations are of varying length, akin in this respect to the Morse alphabet. For example, the letter A will be selected by a dash, short space, dot, short space; dot; B by a dot, long space, dash, long space, dot, dots and dashes being made by positive currents, spaces by negative currents, as in the Wheatstone automatic telegraph (q.v.). The combinations of dots, dashes and spaces representing the different letters comprise what is known as the Buckingham alphabet. For the actual printing of a character, the sixth pulse, corresponding to the space between letters and words in the Morse and Wheatstone systems, is utilized. This is always a negative pulsation. In the preparation of messages for transmission, and in the actual transmission of messages, this system is the same as the Wheatstone automatic telegraph, and if the Wheatstone receiver were employed, the messages would be received as dots, dashes and spaces.

The transmission of the six pulses of alternating polarity of the letter of the Buckingham alphabet operates a polarized relay in the receiver at the receiving station, which relay by its armature controls two circuits, in which are a governing relay, a magnet and an escapement magnet. Imparting, by means of an escapement and step-by-step motion to the sunflower disk of peculiar construction, to such purpose with the co-operation of the governing and depending on the duration of the pulses and the order of their arrival, more selecting relays are operated, and in turn, cause the operation of the type-levers which bring a desired letter on the wheel to the printing position. Hence Buckingham printer is a positive or step system in which an escape-wheel with it the sunflower, is caused by a few six pulses of current, one or more of which are prolonged, to undergo a cycle of six for each letter or character selected and p

The Barclay Page Printer.—This is a modification of the Buckingham printer just briefly described. The operation of the Barclay printer is somewhat similar. In this system, all relays is virtually similar to that of Buckingham. At this point, in the Barclay, the selecting relays, instead of operating the type-wheel shaft, are caused to select one of 30 or 32 electromagnets, which controls or operates a certain typewriter which prints the letter, the being printed by the typewriter in any way, by the aid of electrical devices. May be transmitted by this system by a keyboard manipulated by an operator by means of perforated paper.

Murray Page Printer.—This printer being used on the lines of the British office. The messages to be transmitted prepared somewhat as in the case of method utilized in the Wheatstone au system. The perforated paper sends combinations of electrical pulsations for given letter over a main line and these letters in turn operate apparatus at the receiving station which perforates a paper a manner corresponding to the letters transmitted. This paper is then caused to form a set of metal strips which operation, and depending on the combination of perforations in the paper, select a letter of a typewriter, the message thereby printed in page form. This system is about 103 words per minute. C

the maintenance of exact synchronism between
the transmitting and receiving trailers over
their respective segmental discs — analogously
as in the synchronous multiplex Morse system,
but greater refinement of apparatus and oper-
ation is necessary in the multiplex printer.
Obviously this must be so from the fact that
in the multiplex printer means are provided
for operating the typewriter carriage, printing
the letters, etc.

The code or alphabet employed in this
multiplex printing telegraph system is virtually
similar to the Baudot alphabet. It is known
as a five equal unit alphabet, that is, five im-
pulses of positive or negative current are com-
bined to form a given letter. Thus the letter
A is assigned two positive and three negative
impulses, B one positive, two negative and two
positive units. Each current impulse in the
Baudot code is of equal length and by different
combinations of the five impulses it is possible
to form 31 letters or characters. In the Morse
code the dots and dashes lengths and figures are of varying lengths, and hence
a letter of the Morse code may consist of from
1 to 12 units. The average number of units in
a letter of the continental Morse code is prac-
tically nine units per letter. It has been cal-
culated that this disparity in the two codes
results in an advantage for the Baudot alphabet
in practice of about 65 per cent over the Con-
tinental Morse alphabet in the rate of transmis-
sion over circuits of equal length.

This multiplex printer rendered most efficient
service in France under the direction of the
United States Signal Corps.

Miscellaneous Telegraph Systems.— In ad-
dition to the telegraph systems referred to
herein, many others have been in actual op-
eration during the past century, either ex-
perimentally or commercially, among which
may be mentioned the electrostatic systems
of Compton, Reuss, Reizen, Don Silva, Be-
tancourt, Cavallo; Ronald's synchronous
system; the electrolytic systems of Sorensen
and Coxe; the chemical facsimile systems of
Cassell, Bakewell, Denison and Bonelli's chemi-
ical printer; the chemical dot and dash systems
of Bain, Morse, Anderson, Delany, Dyar;

Telegraph Systems in Practical Opera-
tion.— Wherever the electric telegraph is em-
ployed the Morse system is the one most
generally utilized. In some countries such as
the United States and Canada, Sweden, Portugal,
Switzerland, Egypt, Bulgaria, New Zealand,
India, Australia and South America, the Morse
system is used almost exclusively. In Great
Britain, Italy, Russia, France, China, Japan, the
Morse and the Wheatstone automatic, which is
simply a fast Morse system, are in common
use. In Austria, Belgium, Great Britain, Hungary,
Sweden, Russia, France, the Hughes printer is
in extensive use. In France the Baudot printer
is utilized; also in Italy, Holland and Switzer-
land to a limited extent. In Great Britain,
about 750 Morse ink recorders; 925 Bright's
Bell; 5,000 A B C telegraph, 30 Delany multiplex; and 4,700 single needle apparatus are in operation. All told there are approximately 70,000 Morse sets in operation in the United States alone, 27,045,000 in all other parts of the world. There are in Europe about 1,700 Hughes apparatus; and in Europe and elsewhere about 530 Wheatstone automatic sets in operation. Needle systems; A B C and Bell apparatus are quite largely used in Europe on the railroad and commercial telegraph lines. A page printing telegraph system, termed Morkrum Printer, is also in extensive use in the United States.

It may be remarked that there is a desire on the part of the telegraphing public in all countries to receive telegrams in type and in page form, and as far as practicable the various telegraph administrations are endeavoring to comply therewith. In the United States, as already intimated, the Morse operators in numerous instances transcribe messages by the typewriter as received. In Great Britain the Murray page printer has been adopted by the government, and in Europe generally, where messages are received on paper strips as by the Hughes and Baudot systems, the strips are pasted on blanks in page form for delivery.

Speed of Different Systems.—The average speed of transmission by the Morse manual telegraph may be placed at about 20 to 25 words per minute, although skilful operators attain a speed of 45 and 50 words per minute. The speed by the Wheatstone system on short lines is about 500 to 600 words per minute. By the Hughes an average of about 30 words per minute in one direction is obtained. This system may be duplexed, giving 50 words per minute on one wire. By the Baudot system, operating as a quadruplex, 120 words per minute; as a sextuplex, 180 words per minute. By the Buckingham and the Barclay systems a speed of 80 words per minute, in each direction, may be obtained on circuits from New York to Chicago, with repeaters midway. By the Murray paper, about 30 to 100 words per minute in each direction may be obtained.

Mileage of Telegraph Lines, Wires and Submarine Cables.—In the United States the total amount of pole lines is about 238,000 miles, on which about 1,700,000 miles of copper and iron wire are excited. In Canada there are about 35,000 miles of lines and 84,500 miles of wire. In both cases the various railroad companies also operate a considerable amount of telegraph line (about 250,000 miles of wire) for the movement of trains, etc. In all other parts of the world there are approximately 435,000 miles of telegraph pole line and 1,450,000 miles of wire, exclusive of about 48,000 miles of pole lines and 216,000 miles of wire controlled by railroads. The average size of the copper wire used on telegraph pole lines is No. 12 or 14 B. & S. gauge; that of iron wire, No. 6 or 8. The nature and size of the poles varies in different countries. Cedar is largely used in the United States and Canada; fir in Europe. Poles 30 to 40 feet long and set five feet in the earth are used. Thirty to 40 poles to the mile has been common practice, but the tendency in this country is toward the use of 45, 50 and more poles per mile to obtain greater security against sleet and wind storms.

The amount of submarine cables in parts of the world is about 200,000 miles, this cable being controlled by governments; the remains owned and operated by private companies. All there are about 1,000 submarine cable varying length in different parts of the globe. While, as stated, the telegraph system in the United States and Canada are operated by private companies, the governments of both of these countries have strung and laid for their own purposes a miles of overhead lines and submarine cables. Thus, the United States government has strung its own telegraph lines and cable Alaska and the Philippines. The A.M. lines extend from Seattle, Wash., to N. Alaska, a distance of 3,625 miles, under 1,459 miles of land lines. 2,079 miles of submarine cable and a wireless circuits of 107 miles in length. The government handles all commercial messages on these lines at a fixed charge. The Canadian government owns and operates about 17,000 miles of lines and cables. The bulletin on movements of fish in the waters of the of Saint Lawrence and other shore lines gather with messages relating to weather, antine and signal service, are transmitted by charge.

Administration of the Telegraph.—Administration of the telegraph is in the hands of the government in all parts of the world. The actual management of the telegraph systems of the various countries of the world is, of course, in the hands of the authorities of those countries, but, in general, the disposition of all matters that relate to the regulation of international telegraph are such, for instance, as the maximum number of letters that shall constitute a word, the abbreviations to be used, etc., is reposed in the hands of the International Bureau of Telegraph Administrations, Berne, Switzerland. In fact, however, even the United States and Canada are to some extent under the control of this bureau in so far as relates to the intercommunication of telegrams with countries under the jurisdiction of the bureau. Thus, if the bureau decides the maximum number of letters in a word, companies publish certain telegrams abroad as regards telegrams that may be rented for or that may be rented from wholly within the jurisdiction of the international bureau.

William M. Taylor, Author of 'American Telegraphy and Encyclopedia of the Telegraph.'

TELEGRAPHY Submarine System of communication between steamer by sound telegraph through water. In A. J. Mundy tested an experimental box Boston Harbor, based on the conductivity of sound through liquids by Elisha Gray. Experiments by J. B. proved remarkably successful. Signals exchanged between lightship bell and a seven miles distant at sea. Sound travels through water or liquids than air and is taken advantage of in a practical way.
TELEGRAPHY, WIRELESS

EGRAPHY, Wireless. During the years attempts have been made, with less success, to avail of electromag-

...duction for signaling to a distance wires, by means of what have been induction telegraph systems. Such employ in their operation the well-principle that when an electric current or falling in one wire will develop a current in a neighboring parallel helps and Edison have employed this in signaling to and from moving These systems were in operation for on several railroads in this country. e...even though there was for lack of e. Preece also, in Great Britain, de-

...ral miles in length is strung on poles e. coast of the mainland, a parallel wire being erected on poles along the shore of an island. These wires are placed in the earth, or "grounded," at their respective terminals. By employing a battery, an induction coil and a Morse telegraph key in one of the wires, and a telephone receiver in the other, it is feasible to transmit signals by induction (pos-

...without connecting wires, across an intervening space of two to four miles. In the operation of these induction telegraph systems from 50 to 300 electromagnetic pulsations or waves per second are utilized.

Notable as the results obtained by induction telegraph systems were considered at one time, they have been completely overshadowed by those systems in which electric waves or oscillations of a much higher order, namely, from many thousands to several millions per second, are utilized, and to which systems the term "wireless telegraphy" is now generally applied. The term "radio telegraphy" is, however, also much used.

The growth of present-day electric wireless telegraphy has been comparatively slow and the discovery and development of the art can scarcely be placed to the credit of any one mind. In 1864 Clerk-Maxwell demonstrated mathematically the electromagnetic theory of light, which in effect is that electromagnetic manifestations are due to undulations of the all-pervading ether, of a nature more or less similar to the undulations of the ether which produce the manifestations of light, and that, in so far as they differ, it is mainly a difference as to the number of oscillations per second, the undulations that produce the sensation of light occurring, for instance, at the rate of from four hundred million of millions per second, to seven hundred million of millions per second; while, as just intimated, the electric undula-

...of the electromagnetic theory of light, which involved the exist-

...cient in electric waves in free space, many scientists endeavored to demonstrate experi-

...mentally the truth of the theory. This honor fell to Prof. H. Hertz in 1887. It had been showed by Professor Henry in 1842 and by Sir William Thomson (Lord Kelvin) in 1853 that when a Leyden jar or other highly insu-

...lated condenser is discharged, the previous charge is not dissipated in one rush, but gradually, in a series of oscillations.

It is well known that in an electric circuit containing coils of wire the current is perceptibly retarded in rising and falling, which fact is due to a property termed inductance, which all conductors possess. On the contrary, when a wire possesses electro-static capacity the current is assisted in rising and accelerated in falling. The property of inductance is usu-

...like to inertia, while capacity is likened to elasticity, in mechanics. The shortest elec-

...wave thus far produced is about .15 inch in length. This is still much longer than the longest light-wave and 60 or 70 times longer than the longest dark wave we measured.

In the electric circuits employed in wireless telegraphy the resistance is small. In fact, if the resistance be too great the discharge will not be oscillatory. The time of an oscillation period is expressed by the formula...
made part of an electric circuit, have normally a high resistance, but under the influence of electric oscillations they lose this resistance and become good conductors of an electric current. It is assumed in explanation of this effect that the electromotive forces that accompany the electric oscillations in the circuit cause the filings, by electrostatic attraction, to cohere, thereby making a better electrical contact with one another, thus reducing the resistance of the circuit; hence the application of the term "coherers" to this type of electric wave detector. It was also found that when the filings had cohered they retained their electrical conductivity until they were jarred, or otherwise mechanically disturbed.

In 1894 Dr. O. Lodge (now Sir O. Lodge), in a lecture before the Royal Society, London, showed that the filings coherer could be used to transmit signals telegraphically by placing them in a glass tube and making them part of an electric circuit in which were a battery and a telegraph receiver. A simple experiment when the induction coil was operated at a distance of some yards from the coherer the latter was actuated. In order that the filings should not remain cohered after the oscillations had ceased, the hammer of a bell operated by electric wire could be thrown on or tap the glass tube as long as the electric oscillations continued. An electric bell has generally been employed in the later use of the filings coherer. In 1895-96 Popoff and others utilized the filings coherer as a means of detecting atmospheric electricity, employing for this purpose a vertical wire extending many feet into the air, the coherer being placed between the lower end of the vertical wire and the earth.

Theories of Electric Wave Propagation.— Obviously substances opaque to light obscure the passage of the luminiferous ether waves. Analogously it was thought in the early days of electric wireless telegraphy, that the curvature of the earth or sea between points several hundred miles apart would prove a barrier to electric waves traveling, like light-waves, in straight lines, insomuch as it would not be practicable to obtain masts, or other means of support for vertical wires, of sufficient height to overlook the earth. The experiments of Hertz showed that with wires only 200 feet high signals could be transmitted to points between which there was a wall of earth or water 15 or 20 miles in height, due to the curvature of the earth. A number of theories have been advanced in explanation of this fact. For example, that the waves are propagated around the earth by diffraction or reflection, but these theories are not generally held to be tenable. A theory that meets with most acceptance at present is that the electric waves are propagated as sliding waves over the surface of the earth or sea.

Brief allusion may be made to the supposed action that takes place in and around the Hertz oscillator in the production of free electric waves. The theory is very limited, perhaps not more than 10 or 12 feet at most. These devices, however, demonstrated the possibility of signaling to a distance by electric waves. Not long after the announcement of Hertz's experiments Dr. Brain discovered that metal filings, when thrown together loosely and

\[ T = 2\sqrt{L/R} \]

where \( T \) is the time in seconds, \( 2\pi \) is the ratio of the circumference to diameter (3.1416), \( K \) is capacity in farads, and \( L \) the inductance in henrys; resistance \( R \) being neglected.

The Yankee Salvage Association's tug Forward, which sends ashore the press reports to the vicinity of New Harbor.
elastic hoops, partially flattened out, their ends resting on the rods. One line of force is assumed to be positive, the other negative. These hoops or lines tightening out and their resistance to inductive and vertical wire, for the transmission of signals, and for the reception of signals, a filings coherer, a telegraph relay, batteries and vertical wire. The general arrangement of Marconi's simplest apparatus is outlined in Figs 2 and 3. In Fig 2, I is the induction coil, a is the interrupter, p is the primary wire, s is the secondary wire of induction coil, B is a storage battery of about five cells. K is the Morse key; b b' are the spark balls. The vertical wire A at its lower end is connected to ball b; the other ball b' is connected with a wire leading to the earth. Balls b b' of the oscillator are thus in series with the vertical wire. The terminals w w' of the secondary wire are also connected respectively to b and b'. The receiving apparatus is outlined in Fig. 3. The Marconi filings coherer is shown at k. It consists of a glass tube, suitably upheld, about 1.57 inches long and .1 inch inside diameter. The filings, a mixture of 90 per cent nickel and 10 per cent silver filings, are inserted in a small space between two plugs n, which fit snugly into the tube which is exhausted of air. Small wires extend from these plugs to the outside of the tube. One of these wires is connected with the vertical wire A, the other with a wire leading to the earth. Hence the coherer is in series with the vertical wire. The relay R is in a shunt circuit with a single cell of battery b and the coherer, as shown. The armature lever l of this relay controls the local circuits of the electric bell T and an ink recording register E, which are operated by local battery b' of four or six cells.

The actual transmission of messages is effected by means of key K, Fig. 2. Each time the key is closed the vibrator a starts into operation with the result that electric oscillations are set up in the vertical wire and a train of electric waves is radiated therefrom in the ether. Thus by opening and closing the key for shorter or longer times the train of horizontal waves is broken up into signals corresponding to dots and dashes which are received as such at the receiving station. The operation at the receiving station is practically as follows: Normally the armature lever l of the tapper T is given a tension which holds it against the contact c. Normally, also, the armature lever l of relay R is on its back stop x. Hence at this time the local circuit of battery b' is open. When then the electric waves set up by the oscillator...
TELEGRAPHY, WIRELESS

arrive and electric oscillations are thereby excited in the vertical wire at the receiving station, the resistance of the coherer drops sufficiently to allow the battery \( h \) to energize the relay \( K \) and its lever \( l \) moves over to contact \( x' \), closing thereby the battery \( h' \), whereupon the electromagnet of tapper \( T \) attracts its armature \( l' \), which act opens its own circuit at contact point \( c \). At once the armature of \( T \) flies back on its contact point, at the same time striking the tube, decelerating the filings and demagnetizing relay \( K \), whose armature lever returns to its back stop \( x \). Immediately, however, the filings again cohere (assuming that the oscillations continue), with the result that \( K \) is again magnetized, the actions just described being repeated many times in a second. Hence, while the oscillations are being received the tapper keeps up a buzz or hum, which stops when the oscillations cease. Likewise, while the oscillations continue in the receiving vertical wire the inking register \( E \) is actuated and dots and dashes are impressed on the paper strip. The paper strip is started and stopped automatically, by devices well known in telegraphy, when signals commence and when they cease. Consult Mayer, "American Telegraphy and Encyclopedia of the Telegraph" (p. 373).

Detectors.—It was early evident to those most concerned in the practical operation of wireless telegraphy that a detector which would "open" on the occurrence of electric oscillations and "close" without tapping when the oscillations ceased was desirable. Such devices were not long in forthcoming. They are termed detectors.

One of the first detectors used in wireless telegraphy is due to Castelli. Detectors have also been devised by Marconi, DeForest, Fessenden and others. The Castelli detector is outlined in Fig. 4. It consists of a glass tube

![Fig. 4. — Castelli Detector.](image)

K, 1.7 inches in length, a carbon rod \( c \), a plug of iron \( t \) within the tube, and a small drop of mercury \( m \) placed between \( c \) and \( t \). The rod \( c \) and plug \( t \) are adjustable within the tube by the screws \( k, h, A \). \( A \) is the vertical wire which is made a part of the coherer circuit. A telephone receiver \( t \) and a small battery \( h \) are placed in a shunt circuit around the detector. Normally, the imperfect contact between the mercury and the carbon causes a high resistance in the detector, but when electric oscillations occur in the circuit the mercury and the carbon cohere and the resistance falls very rapidly. The consequent variations of current in the shunt circuit produce sounds in the telephone receiver of long and short duration corresponding to the dashes and dots transmitted. This detector was used extensively in the Italian navy and was used by Marconi in some of his trans-Atlantic experiments.

Among other detectors are the carbide, due to General Dunwood of Washington, D.C.; the DeForest Audion, and the Silicon detector of Mr. G. W. Pickard of Amersbury, Mass. The Dunwood detector consists of a small crystal of carborundum clamped at its edges between two metal electrodes or terminals. It is placed in circuit with a small battery and a telephone receiver. Its operation appears to depend on the heat, due to the local battery, at the minute points of contact, which heat reduces the resistance of the carborundum. Incoming oscillations affect this resistance and thus produce sounds in the telephone. The sensitivity of this detector is somewhat greater than the filings coherer. It possesses the advantage for shipboard use that jarring does not disturb its operation.

The Silicon Detector.—Detectors of this type are now termed crystal detectors. The detector employs in its operation the principal of the thermo-electric couple. (See Thermoelectricity). The electrodes or thermo-electric couple employed by Mr. Pickard in his receiver are pure silicon and a metallic element of low resistance under a certain mechanical pressure. This couple is placed in the receiving oscillating circuit in which is also placed a telephone receiver, but no battery. According to the invention the received oscillations are converted into heat at the thermo-electric couple, the amount of heat developed being in accordance with the CR law, the energy of which is converted into direct electric current which are heard in the telephone receiver as sounds. Tests by Pickard of a number of the best known electric wave detectors show that the amount of energy required to give a just discernible dot (or sound) in the telephone receiver is as follows: Electrolytic detector to .000060 Erg.; Magnetic detector .000100 Erg.; Silicon detector .000150 Erg.; Carborundum detector .000400 Erg.

Vacuum Tube Detectors.—The useful detector of wireless telegraphy and telex signals today in the vacuum tube detector, which has been known for a number of years, is the vacuum tube detector, in which the air or gas surrounding an incandescent wire or filament is ionized due to electrons escaping from the incandescent body. The hot filament was discovered in the last century, but to this fact, the correct explanation was not forthcoming at that time. Thus in Houston's "Electrical Directory," published in 1892, the Edison effect is defined as follows: "An electric discharge which occurs between one of the terminals of the incandescent filament of an electric lamp placed near the filament but disconnected therefrom, as soon as a certain difference of potential is reached between the lamp terminals. The effect of the discharge is to produce a current in a circuit connected to one pole of the lamp terminals and another metallic plate, as may be shown by means of a galvanometer." The vacuum tube detector is based primarily on the Edison effect. Apparatus and circuits to show this effect are outlined in Fig. 5. An electric current from a battery \( A \) heats the filament or wire \( F \) to a desired temperature, when it is found that a platinum plate \( P \) adjacent to \( F \) becomes positively electrified to a few volts, as shown by a galvanometer \( G \), indicating that the intermediate gas is ionized or rendered electrically conducting. In the later use of vacuum tubes for X-ray work, wireless
TELEGRAPHY, WIRELESS

Gratory and telephony, very high vacuums used which give a pure electron discharge, greatly improved results, especially perhaps X-ray work.

The number of electrons flowing from the plate to the plate in a high vacuum tube depends on the temperature of the filament and potential or space charge of the plate. The amount of current in the filament to plate circuit depends on the number of electrons received or emitted from the filament and has an calculated to correspond to 10^8 electrons per amper. After a certain increase in the operation of the filament, which is limited by strength of its material, and at a certain active potential of the plate, saturation is reached. The flow of electrons, which are asked to be negatively electrically charged particles, is apparently from the filament to the plate, which is charged with positive potential, so the current flow is from the plate to the filament.

As already noted the bulbs used in this serve require an exceedingly high vacuum for proper operation. It is also important that the filament and other metallic elements of tube be free of gas.

Fleming Valve Detector.—Fleming improved upon and utilized the foregoing Edison device by making it a wireless detector known as the Fleming valve or current rectifier. Fig. 6 shows the circuit of the detector. Plate W is part of an oscillation circuit S, C, F, W. Filament F is brought to incandescence by the battery B; this releasing electrons at the filament. Incoming oscillations from the aerial due to arriving Morse signals set up alternating currents of positive and negative potential on plate W. When the plate is charged positively the negative electrons are drawn over from the filament, increasing the potential on W, which in turn charges the condenser C at that instant. When the plate W is charged by incoming negative oscillations electrons do not pass from F. Hence positive or unidirectional currents only are allowed to pass. Between the positive charges of plate W, the condenser C discharges through the telephone receiver T, thereby reproducing the transmitted dot and dash signals.

The De Forest Audion.—To the Fleming valve de Forest added a metal grid G (Fig. 7) between the filament F and the plate P, making it a three electrode tube VT. He also added a potential battery PB to plate P, which combination produces remarkable results. De Forest termed this device the audion, from the words audible and ion. A is an aerial; p, s, are the primary and secondary coils of the tuning or receiving transformer L. TC is a variable, or adjustable, tuning condenser. C is the grid condenser. The grid G intercepts the electrons flowing from F to P, and it is found that a given variation of voltage in the grid produces a greater variation in the plate currents than is effected by a similar variation of potential on the plate P with the grid removed. The incoming oscillations from the aerial in the grid-filament circuit are repeated or relayed into the grid-plate circuit more or less amplified. This fact constitutes the audion an amplifier of current and consequently of sounds, and because of this relaying property the audion is also termed an electron relay.

Figs. 6 and 7 may be regarded as showing theoretically the ordinary wireless receiving circuits in which the respective detectors indicated are employed.

Another way of regarding the operation of the vacuum tube is to assume that the heated filament sets up a negative electromotive force due to the presence of negative electrons. The potential battery PB produces a positive potential at the plate. The conventional explanation then would be that the current flows from the positive potential at the plate to the negative potential at the filament; the battery in this case providing the supply of electrons or in other words, the current. On this hypothesis a reduction of the negative potential at the filament, the potential at the plate remaining the same, will cause a reduction of current between F and P. Similarly a reduction in the positive potential at the plate will reduce the current. By obtaining control of the potential of the plate...
and grid a variation in the output of the tube is obtained. The grid element in the tube provides a means of varying the plate potential, and reversely a variation in the plate potential affects in an opposite sense the potential of the grid.

The three electrode vacuum tube has recently undergone great improvements at the hands of many experimenters, and it is now not only utilized as a detector and amplifier of wireless telegraph and telephone currents, but also as a generator of high frequency electrical oscillations and a modulator of radio waves in Wireless Telegraphy (q.v.). This tube is also employed as a repeater or relay in long distance wire telephony and indeed it is largely due to the amplifying and relaying properties of this instrument that trans-continental telephony is commercially possible.

There are at least three variations of this tube now in use, termed, respectively: The kenotron, the plotron and the dynatron. The kenotron rectifier utilizes the unidirectional property of the current between a hot and cold electrode in vacuum. The plotron utilizes the space charge property of this current which allows the current to be controlled by the electrostatic effect of a grid. The dynatron utilizes the secondary emission of electrons by a plate upon which the primary electrons fall; it is, as its name indicates, a generator of electric power and feeds energy into any circuit to which it is connected. For fuller information on this subject the reader is referred to the Journal of the Institute of Radio Engineers, September 1915, and to the bibliography appended thereto. For details relating to and for other examples of circuits in which the three electrode tube is utilized see Telegraphy, Wireless.

The Vertical Wire or Aerial—Marconi's first experiments in wireless telegraphy were made with a vertical wire 20 feet high at the sending and receiving stations. With this height of wire he transmitted signals one mile. With wires 40 feet high signals were transmitted four miles and with wires 80 feet high 16 miles. Many different arrangements of the aerial wires are now employed. For instance, in a number of wireless installations 20 wires about No. 16 gauge are suspended from a long strip of wood, which is upheld by insulators supported by a rope between the tops of two masts about 150 or 200 feet high. The wires, two feet apart, drop vertically to a similar wooden strip, where the wires are joined together and led into the instrument room. In other cases the wires are suspended from towers by well-insulated arms and are kept apart by wooden spreaders until near the ground, where the wires are connected and then are carried into the operating room. In still other cases a single mast is employed, from the top of which a number of wires are suspended. Each wire is attached, at a distance of about 50 feet from the top of the mast, to a guy-ropes, which is itself attached to an anchor post in the earth, 40 feet or more from the base of the mast. The guy-ropes thus drawn the wires away obliquely from the mast, then at its point of connection with the guy-ropes each wire is directed to the mast. Between all wires the insulator. The effect of the mast as a base and no spreaders is required.

In Fig. 8 are shown various ways in two or more aerial wires may be used. The wires may be of different lengths depending on requirements. In the arrangement shown at c indicates a four-wire arrangement is a cage arrangement of four, six or eight wires in which the wires are held at a hoops; g is a box method in which wires are separated by a wooden block. The plan shown at c is much used. The in this case are held apart by wooden spr}

![Diagram](attachment:image.png)
TELEGRAPHY, WIRELESS

If closely adjacent parallel wires is not, proportionally to the number of such ut is equal, roughly, to the square root number of wires. The capacity of a wire 1 inch in diameter and 100 feet h is .0002 micro-farad (Fleming). Ordinary service the grounded antenna found to operate satisfactorily, but circuits the direct earth connection some disadvantages. Thus variations existence of the earth connections added difficulties in the way of maintain tuning or syntony. (Described sub.). Shipboard practice the aerials A are try extended in a sort of cage arm C from the heads of the fore- and stern as outlined in Fig. 9. The cage con-

![Fig. 9. — Shipboard Aerial Wires.](image)

arrangement the horizontal wires, which possibly give a directive tendency to the aerial waves, are connected at the far end. The horizontal wires are supported by porcelain insulators K, about two feet in length, and are attached to the masthead M by suitable tackle T, which uphold the spar P 15 feet in length and to which the insulators are fastened. The horizontal wires are two and five feet apart.

Condensers.—The condensers used in transmitting circuits for installations up to one or two kilowatts are generally of the Leyden jar-type. Such jars, 16 inches high by 5.25 inches in diameter, have a capacity of .004 micro-farad. For more powerful installations, large plate-glass condensers immersed in oil, contained in insulated tanks, have been used by Marconi, De Forest, Fessenden and others.

Generators of Electric Oscillations.—The need of greater radiating power in long distance wireless transmission than is obtainable from the ordinary induction coil, as well as the unreliability of the interrupters of such coils, when used with large currents, which soon wear out the contact points, has led to the adoption of special types of transformers. Instead of battery power also, alternating current generators are employed as the source of electromotive force for these transformers. The power of the generators may vary from 1 kilowatt to 300 or more kilowatts. The rate of alternations of the transformer depends on the frequency of the generator. The electromotive force in the primary circuit of the transformer may be from 50 to 200 volts, which is greatly increased at the secondary terminals of the transformer; in some cases to 20,000 or 50,000 volts. In the case of the New Bruns-
wick, N. J., transatlantic station a 60-cycle 24,000-volt current in the secondary circuit of the transformers is employed to charge the large glass condensers, which in discharging produce the high frequency oscillations thrown upon the aerial wire.

In addition to the spark gap method of generating high frequency oscillation in wireless telegraphy, as described in the foregoing, by means of induction coils, several other methods are now employed, among them the carbon arc generator, the high frequency machine alternator and the three-electrode vacuum tube oscillator, to which reference will be found in article on (Wireless Telephony (q.v.)). Consult Anderson and Elliott, 'Poulton Book' (Electric Work, 30 Aug. 1919); 'Trans-Atlantic Radio Communication' ('Proceedings,' American Institute of Electrical Engineers, 1 Oct. 1919). Marconi has also developed a successful method of obtaining sustained oscillations by means of rapidly rotating metal disks which by suitable arrangements of capacities and inductances set up rapid charges in an oscillation circuit. For a description of this oscillator consult 'Transactions,' Royal Institution (London, March 1908) or Mayer, 'Wireless Telegraphy and Telegraphy' (Part 2, page 9).

Syntony or Tuning.—An important defect of wireless telegraphy in the simple form thus far described consists in the fact that but one message can be sent at one time, for it is that if it is attempted to send two messages at once in the same vicinity, the signals will clash. Many inventors have striven to overcome this

![Fig. 10.—Shipboard L Aerial.](image)
defect, among others Lodge, Marconi and Slaby. The plan followed by these workers has been that of employing a synergetic or tuning method; that is, a method by which the transmitting and receiving circuits are adjusted or attuned to a fundamental rate of electric oscillations, to which rate of oscillations and no others the receiver so attuned will respond. This is done by taking advantage of the fact that the rate of oscillations, or the frequency of an electric circuit is proportional, as already noted, to the inductance, capacity and resistance of the circuit. Hence by varying the capacity or inductance of the tuning circuits any desired rate of oscillation is obtained. Tuned circuits are termed selective circuits, since by sending out a given rate of waves any desired tuned circuit within mixing signal may be selected as the receiving station.

Tuning also possesses the advantage that the benefits of resonance may be obtained by its use as follows: It is known that a vertical wire grounded directly at its lower end is an excellent radiator of electric waves, but as it possesses very little capacity its oscillations are quickly damped as indicated in Fig. 11 and it is only the first few oscillations that are of sufficient strength to affect a receiver. When capacity and inductance are added to a circuit in certain proportions it may be made a persistent vibrator (Fig. 12) and consequently a given amount of electrical energy expended at the transmitting end producing a succession of waves of more uniform amplitude will have a cumulative or resonant effect upon a receiving circuit of equal capacity and inductance, and will eventually cause it to respond to the waves emitted by the transmitter, while an untuned receiving circuit containing a detector as sensitive as the first one, would probably not respond to those particular oscillations. In the case of tuned circuits, this is doubtless because the faintest oscillations, or electromagnetic forces, excited in the receiving circuit are resonantly amplified by the incoming waves of a selected frequency until they affect the detector.

As a rule, the spark-gap and the receiving apparatus of untuned circuits are connected directly to earth as indicated in Fig. 13, in which \(A\) is the antenna; \(b\) is the spark balls or knobs; \(a\) is the spark-gap; \(S\) is the secondary and \(P\) is the primary of an induction coil or transformer. In such an oscillating circuit \((A, b, b)\), the oscillations are quickly damped. In the case of tuned circuits, or where, at least, the effects of resonance are desired, there is provided a closed oscillating circuit which is separated from the capacity and inductance of the transformer. Such an arrangement is outlined in Fig. 14. The closed circuit in this case consists of the spark-gap, condensers \(c\), and the primary of transformer \(T\). In practice the condensers and the inductance coils are made adjustable, so that the capacity and the inductive may be varied at will. Best results are obtained when the oscillating circuit and the vertical wire have equal fundamental oscillation periods, or when the one is a multiple of the other. Oscillating circuits arranged as in Fig. 13 are said to be tightly coupled. When arranged as in Fig. 14 they are said to be loosely coupled.

In addition to the fact that the oscillations on an ordinary vertical wire are quickly damped there is the further fact to be considered that the oscillations set up by a spark-gap transmitter are not continuous in the strict sense of the word, since there is a perceptible time while the oscillation circuit is being charged, the breaking down point of the air-gap, during which the oscillations tend to die out. Several inventors have striven to obtain a transmitter capable of supplying undamped or practically uniform oscillations to the oscillation circuit. Poulsen has developed some improvement in this direction by a modification of the Duclieu singing arc (described in his British patent No. 21,620). (See TELEGRAPHY, WIRELESS). Briefly it consists of an arrangement in which an arc lamp supplied by a direct current is placed in parallel with a capacity and an inductance. When the capacity and inductance are suitably chosen, rapidly alternating currents are set in this arc which produce a tone—hence name singing arc. In Poulsen's modification, this arrangement the negative electrode of the arc is carbon, while the positive electrode is copper, the arc being enclosed in a box containing hydrogen gas. The arc is shunted by a capacity and inductance and rapidly alternating currents are continuously set up which are thrown on to the vertical wire in the usual way. With the Duclieu arrangement the frequency of oscillation was about 10,000 to 15,000 periods per second—too low for utilization in wireless telegraphy. A much higher frequency is obtained by the Poulsen arrangement which is attributable to the arrangement. Further the cooling of the electrodes (an essential first noted by Elihu Thomson, in United States Patent No. 500,630), the copper electrode is made in the shape of a hollow ring through which water is passed. Tests have demonstrated that by this method of setting up undamped oscillations it is possible to signal over greater distances with much less electrical energy than is required with the spark-gap method.

Quenched Spark Transmitter.—Weiss in 1906 discovered that very powerful discharges possessing advantageous properties for wireless telegraphy could be obtained from very short spark-gaps. To avail of this discovery Van der Waerden employed as an oscillation generator, a device consisting of a metal box containing two copper plates separated by a very thin sheet of paper provided with a small aperture in its centre. The terminals of the usual charging electromotive force are each connected
The velocity $V$ of propagation of the waves being equal to that of aves, 186,000 miles per second, the wave then equals velocity divided by frequency wave length equals,

$$V \sqrt{K L} = 2\pi V \sqrt{K L}.$$  

Ordinary practice resonance is indicated loudness of received signals in the tele-receiver.

of the early wave meters, the Donitz in Fig. 15. A brief description of the will explain the general principle on wave meters operate. The Donitz wave consists of a coil of wire $C$, about eight in diameter that may be placed in the oscillation circuit to be measured, anode, coil $C$ which may be a loop in an circuit. Coil $C$ is in series with a con- and another coil of wire $c$, $c$ is in relation to a smaller secondary wire the circuit of which is a small heat wire fixed in one end of a U-shaped tube $T$, filled with a colored liquid. The capacity is made of two sets of semi-circular metal one set fixed, the other set movable to or fixed plates, the whole being contained as case and immersed in oil. The moves are operated by means of a knob $N$ to which is also attached a pointer $P$, which moves around a graduated scale $S$. The capacity $K$ of this oscillation circuit varies with the

![Fig. 15 — Donitz Wave Meter.](image)

![Fig. 16 — Marconi Tuned System.](image)

![Fig. 17 — Marconi Tuned System.](image)
up transformer and is used to increase the efficiency of the apparatus by enhancing the electromagnetic forces acting upon the coherer; availing of the fact that there is a node of electromagnetic force and a loop of current at the foot of the vertical wire—that is, at that point the electrostatic energy is at minimum while electromagnetic energy is at maximum. K is the Marconi filings coherer, which is in series with the secondary coil s s of the jigger. A small condenser c is connected as shown, forming a short circuit for the oscillatory currents across condenser c, thereby precluding any diversion of these currents through the relay R. This is a polarized relay of from 1,200 to 10,000 ohms resistance, in the circuit of which is a single cell b. The relay is usually inclosed in a cylindrical case to exclude dust. Some of the relays used for this work will respond to a current of 0.1 ampere of an ammeter. In practice this relay, the jigger, the coherer and tapper are enclosed in a metal sheathed box to prevent the action of external electric waves upon the coherer. For the same reason the local contacts of the relay and tapper are shunted with resistances, not shown in the figure. The Morse key employed is massive, with front and back contacts which are insulated from one another. It is provided with a large vertical handle to protect the operator against shocks. The use of the coherer for commercial use has been displaced by more modern devices.

The Fleming Long Distance Transmitting Circuit.—In Fig. 18 is shown diagrammatically an arrangement, designed by Prof. J. A. Fleming for the Marconi Wireless Telegraph Company, to be used in long distance transmission. In the figure, D is a 500 or 1,000 volt alternating current generator of 10 or 20 kilowatts capacity, and having a frequency of about 50 per second. T, T' and T'' are transformers. The primary circuit of T is in series with the generator D, and the coils i, i'. The transformer T raises the electromotive force to about 20,000 volts, charging the condensers C, which discharge across spark-gap S, setting up oscillations of a high order in the oscillating circuit O, S, C, T'. These oscillations are again transformed to higher voltage in the secondary of T", which in turn excites the vertical wire A, the discharging in the oscillating circuit O', S', C', T", still further increases the electromotive force thrown upon the wire or wires A. The estimated electromotive force obtained at the vertical wire in this way is about 100,000 volts. These condensers are of glass immersed in oil and the transformers are of special construction to withstand these high pressures and to have desired capacity and inductance. To directly opening and closing the primary circuit of the transformer T, the two contacts I, having movable iron cores, m, m', are in that circuit. The iron core m' of i is adjusted so that as much current as may safely pass through the primary of T shall have no flow in the circuit. The core m of i is made of its full length in the coil, and its iron is sufficient to stop all flow of alternating current in the circuit. This coil may, however, be short-circuited by the key K, in dot and signaling, at which times the current attains full value. Hence the circuit is not opened at the usual sense, but to avoid sparking the exact points of key K may be immersed in oil.

In Fig. 18a is shown theoretically a transmitting apparatus and circuits employed in ordinary ship and land stations.

![Fig. 18a.—Modern Transmitting Circuit. Lead on board Station.](image-url)

**Fig. 18a**—Modern Transmitting Circuit. Lead on board Station.

is a motor-generator controlled by a starter not shown. The motor is usually supplied with current at 110 volts pressure. The generator G may develop from 110 to 500 volts as desired. QS is the spark-gap (quark type). K is a Morse key in the primary circuit of the transformer T. Specially designed keys for this work will open the circuit with excessive sparking with a current of 25 and 110 volts. The voltage in the circuit C', OT, QS, may be raised to 10,000 or more by the transformer T. C represents Leyden jars or condensers and the oscillation circuit is connected by loose contact to the aerial A, by means of oscillators O and T. The oscillation transformers OT may consist of two independent heavy bar copper wire with widely separated spirals and with one of the coils movable side to side of the other for varying the coupling. Clips m are also provided whereby more or less of the coils may be connected in the tuning. L is a tuning inductance in the circuit C. is a condenser used for short wave work. It may be cut out as in the figure by CS. A is a hot wire ammeter placed in the aerial to show when oscillations are thrown upon the aerial and to indicate the strength of current therein. Resonant circuit between the circuits when h is at maximum. S is a safety device to discharge excess current in the circuit to ground. A motor starting arrangement for the motor-generator is also described in the author's work *Telegraphy and Telephony* (page 103).
TELEGRAPHY, WIRELESS

Motion, Directive Signaling and Finders.—In ordinary wireless telegraphy, the electric waves are radiated from an antenna in every direction, as, for instance, from light waves from a lamp on a pole or a lighted candle in every direction. Attempts have been made to reflect and direct electric waves, but by means of metallic or other means. These attempts were not successful in meeting the requirements of the reflecting mirror in compensation with the length of the wave to be radiated, and that the mirror should not be further than a quarter of a wavelength from the oscillator or source of the wave. This difficulty results from the fact that the electric waves used in telegraphy and telephony are of the order of 100,000 per second. On the contrary, the length of a wave is so infinitesimal that the smallest possible to construct, or even particles of light large by comparison with light waves, have been met with in the direct signaling by methods differing from the mirror reflection method. Before some of these methods it may be pointed out that the theory of wave undulations or oscillations of simple form are frequently shown graphic-sinusoidal curve, or sine wave, describing the motion from the point to a wave of a point on the surface of a rolling wave, or from the nade by the movement of a pencil through the movement of the pencil corresponding point moving back and forth along the edge of a circle. In Fig. 19, the vertical may represent such a back and forth

The line AB represents the forward motion of the wave, and x x' the distance covered by each cycle of the wave, this corresponding to the distance x x'. In wave motion, it is understood that the particles of the medium do not move forward with the wave, but merely rise and fall like chips on the surface of a pond as the waves pass under them. As the wave progresses, each particle of the medium in turn rises to the crest and drops to the bottom of the wave. In a liquid, the medium it is assumed that the particle is displaced from its zero position by a force or strain which it resists with a counter force termed stress, the stress varying with the extent of the displacement, and tending to restore the particle to zero position. The position of a point or particle at a given instant relative to any fixed position is termed the phase, and the difference of position of a given particle relative to another particle during its motion over a circle is termed phase difference. Thus a particle at b will pass through point C in advance of particle a, the direction of motion being as shown by the arrow, and their phase difference when measured as an angle will be equal to the difference of the angles made by their radii with a fixed line A x. For example, the difference of phase between a particle at C and one at x is 90°, or one-fourth of a wave length; while a particle at C and one at A will have a phase difference of 180° or one-half wave length. When two particles pass through the same point at the same time they have no phase difference. Any two particles one wave length apart are said to be in the same phase, and two waves of the same frequency whose corresponding parts are moving in opposite directions with the same velocity are said to have a phase difference of 180°. For present purposes the broken curved line in Fig. 19 may be considered to represent the contour of an electric wave, while that portion of the curve above the line x x' may represent an electric positive force or sign; that below the line a negative force or sign, and the magnitude of the force of the wave at a given point and instant may be represented by the length of the vertical lines between x x' and their point of intersection with the curve. In this view, waves of different or equal phase and magnitude and agreeing or opposing in direction or sign may be caused to assist or neutralize one another, more or less; some instance of which is given herein, and analogous instances of which may be found in textbooks on light and sound.

Electric Wave Localizer.—A device due to John Stone Stone for determining the direction from which wireless telegraph signals are emanating is shown in Fig. 20, theoretically. In the figure, A represents vertical wires placed on a common axis a, and in series with which are coils of wire x y respectively. These coils are so wound that when oscillations of equal strength and direction simultaneously pass through them from wires V V' the coil z, which is in inductive relation to those coils, will not be affected. When the oscillations in coils x y are in opposite directions or differ in strength coil z will be affected. Coil z is in series with detector d, condenser C and telephone receiver t. In order to obtain the maximum effects of the wave energy the wires V V' in this arrangement are placed the distance of half a wave length apart, which distance can be ascertained by means of a wave meter. Assuming the length of the arriving waves to be
50 feet, the wires 25 feet apart, and that their plane is in the line of motion of the advancing wave, the wires will receive the waves at a phase difference of 180° or half a wave length. Hence the oscillations in the wires due thereto will be of equal strength, say, 10, as indicated in the figure, but opposite in sign, or direction, in coils $x$ $y$, and the coil $z$ will be inductively affected to a maximum extent. If the wires upon $z$ are zero which will be with of the wires is at right angles to of the arriving waves. According to the apparatus of this device has never been used with a wave length exactly twice the distance between the two aerials or verticals $V$ $V'$. The object in having the wave equal to twice the said distance is that arrangement gives maximum intensity signals, the signals under all conditions to be maximum when the plane of the wave right angles to a plane down through antennas; the signals being canceled coils $x$ $y$ when the plane of the waves is with the plane passing through the vertical wires. Consult U. S. Patent No. 716,133, covering this device.

**Bent Antennas in Directional Signaling**—De Forest states that vertical wire to which is attached a horizontal wire signals are received by of the detector in the vertical wire, the sum of which signals appear to vary according to the position of the wires approach or from a position of parallelism with the direction of travel of the waves. The various arrangements of $T$ and $L$ antenna so largely employed for capacity on board ship and in stations correspond more or less to a going device but practical experience definitely indicate that in ordinary working the signals are affected favorably otherwise as regards the directive effect on signaling by such arrangement of the aerial wires.

Marconi has made numerous experiments relative to directive wireless signaling and found that by placing a large number of $w$ arranged as an $L$ aerial, or bent antenna with the open end pointing away from the distant station the direction of effective $v$ may be largely controlled; also that by similar antennae the reception of signals is improved. Braun, Artom and others have experimented with directive aerial devices, an account of which may be found in textbooks on wireless telegraphy.

**Bellini-Tosi Directive System and Devices**—Bellini and Tosi in their experiments in France

strength and direction will then be set up in the vertical wires, the effect of which on the coil $z$ is nil, owing to the differential winding of the coils $x$ $y$. To determine then, the direction of arriving waves it is only necessary to turn the wires $V$, $V'$ on their axis $a$ until the combined forces of the oscillations in coils $x$ $y$ a triangular nearly closed aerial in of rotation on its axis, using a receiver somewhat similar to those described. Like other experimenters Tosi found that the strength of signals was a maximum when the triangular transmitting circuit $v$
m of the receiving station, and that upon the triangle on its axis directing its way from that station the strength of gradually weakened and was always zero at the extreme distance of the retransmitted wave. To avoid the difficulties involved in use of movable aerials for directive purposes, inventors devised the plan of using sets of triangular aerials, placed at right angles to one another, as outlined in Figs. 24, in which W E indicate the two upper parts of the triangle and N S' similar sides of the latter. In connection with this arrangement of aerials a device termed a radio- meter n w C is utilized in which will be certain resemblance to the Stone localizer as previously described. The radio-photometer consists of two fixed coils n w at right angles to each other, and of a central coil C movable pivot in any direction within the coils W E. When the atmosphere was not coil C, 1, 23, is the primary of an oscillation meter with two secondaries, n w. When reception of signals, as in Fig. 22, coil n serves the secondary of two primaries n w. At time inductive effects will be inappreciable in coil w, but will be a maximum in coil n, a direction of transmission will be N S. Primary coil is placed parallel with coil direction of radiation will be W E. If sired to send signals in any direction between W N or E S, effect is by placing n the desired position in case each w will be acted upon proportionately to coil C, and the direction of radiating will be a resultant due to the combination of two electromagnetic forces developed by coils n w, virtually according to the law parallelogram of forces. In Fig. 21, for e, with coil as shown, the resultant directed be as indicated by the dotted lines e length N s, respectively represent the assumed magnitude of component forces in the direction indicated by lines; or if the coil C be turned in the m of dotted or resultant line, the mag of the component force due to coil w be reduced by the amount indicated by intersecting dotted line at e, while the common force due to coil n would be indicated dotted line n. Reversely when the radiometer is used as a receiver or direction Fig. 22, the incoming wave fronts will the closed aerial oscillation circuits, as stated in connection with Fig. 20. If an entering wave front is in the plane of coil n only will be affected and coil C ed by the operator until maximum current signals are obtained. If, on the other hand, wave front is advancing from a directway between N and E, the coils n w equally affected, and the position 1 C will be as indicated by the dotted line 8. The foregoing described device added importance from the fact forms the basis of the now well-known u-Bellini-Tosi Direction Finder. (Con-
TELEGRAPHY, WIRELESS

$A$ is the aerial. $B$, $B'$ are branched circuits from the aerial, coupled differentially, to a detector circuit $C$, $C$, $C$. $T$ is a head telephone receiver. The assumed operation of this device was that if one of the branch circuits, say $B$, be attuned to arriving signals and the other branch, $B'$ be not so attuned, the attuned circuit would respond to arriving signals while the untuned branch would not respond, and, further, that the static currents, being forced vibratory, would pass through both branches in equal strength and would, therefore, cancel each other in the differented coils. It has been pointed out, however, that the static currents are also responsible to tuning of the branches to different rates of oscillation which prevents the desired cancellation of the static currents in $B$, $B'$, hence the static noises will be heard in the receiver. Consequently, any apparent benefit derived from this arrangement must be due to the loose coupling of the circuits, which diminishes the strength of the static currents.

Dickman designed a protective shield of wires to be placed over and around the wires of an $L$ antenna to cut off the static currents from the aerial and divert them to the earth. This device is expensive since it practically duplicates the regular antenna, but it largely diverts atmospheric currents from the aerial proper. It does not, however, divert horizontal electromagnetic stray lines from the antenna.

**Weagent Anti-Static Device.**—The principle involved in this device is the outcome of Weagent's remarkable discovery that the statics producing the greatest interference in wireless telegraphy are not parallel with the waves due to radiation from wireless telegraph stations, but are vertical in direction. It is beyond the scope of this article to give more than a brief description of the methods which Mr. Weagent has invented to avail of this discovery. For a full description thereof the reader is referred to the Journal of the Institute of Radio Engineers, March 1919.

Granting the accuracy of Mr. Weagent's assumption as to the vertical direction of static currents or waves the direction of their propagation will be at right angles to that of advancing wireless telegraph waves. The problem then was to separate the wireless signal waves from those due to statics in the antenna circuit.

The Weagent arrangement of circuits and apparatus to effect this result is shown theoretically in Fig. 25, the explanation of which will perhaps be simplified by reference to the description of the Stone Direction Finder and the Bellini-Tosi goniometer, herein. For his purpose Mr. Weagent arranged two loops $l$, $l'$ of aerial wires supported on poles, the receiving station being at $X$. The length of each pole is, say, three miles, although the inventor experimented with loops of varying less than three miles. The supports are 30 feet high. The wires of the loops are spaced 15 feet apart on the poles. Each loop is connected at $X$ in series with a condenser $C$ and one primary coil $p$, $p'$ of a radio goniometer, the secondary coil $s$ of which is coupled with the tuning coil $t$ of a wire receiving circuit containing the usual variable condenser $m$, detector $d$, battery $b$ and phone receiver $T$. Variable inductances $i$ and resistances $r$ are placed in the loops $l$, $l'$ for adjustment purposes. The coil $s$ may be rotated into a desired position.

The vertically moving static waves are indicated by the downward arrows $a$, $a$, the two static waves due to wireless signals indicated by the horizontal arrows $a$, $a$. Since the static waves cut both of the loops simultaneously the currents set up by them in the primary coils $p$, $p'$ of the goniometer (bound oppositely to each other) are in phase and produce no effect on the secondary coil $s$ of that apparatus. But the arriving signal waves cut the respective loops at different times with the result that the currents set up thereby are not in phase and a preponderant current is produced in one or other of the primary coils of the goniometer, which current in the secondary $s$ of those coils is heard in the detector circuit as in a wireless telegraph operation.

Mr. Weagent in his paper states that to obtain tuning in the loops an inductance coil $i$, $i$ of 30 millihenrys is placed in the upper wire of each loop and best results are obtained when this inductance is placed near the middle, when the tuning is at a maximum. A similar coil placed in the lower wire of a loop effects no change in tuning. Experiments showed that the coil of 30 millihenrys was best for a wave-length of 12,000 meters while a coil of five millihenrys gave best results for a 6,000-meter wave. Both values, however, were satisfactory for either length of wave with loops three miles in length. While the foregoing device was efficacious in getting rid of the vertical statics termed grinders, it was found, in long-continued tests.
by Mr. Weagent with a two-wire system installed at Lakewood, N. J. Interference due to clicks or horizontal could not be altogether eliminated by a wire loop arrangement. Mr. Weagent, however, termed grinders as such produces in the telephone receiver ainoous rattle with occasional crashes, and are noticeable in warm than in cold weather. On the other hand, clicks, which are spaced crashes in the telephone, are noticeable in cold weather, but they are continuous in their action as grinders. It is found that with the two-wire arrangement clicks interfered more with the reception of signals emanating from comparatively low power stations as far afield as Ireland, and the Eiffel tower, and that it is devised to reduce the effect of the so-called weakened signals. On the other hand, clicks were not of sufficient strength to impair signals received from the powerful stations at Carnarvon, Wales, or Germany.

Means of another device due to Mr. Weagent and shown in Fig. 26, it became possible to eliminate the statics due to clicks to the extent that the signals from the weaker stations were easily readable. Since it was demonstrated by the experiments referred to, the two-loop aerial picked up vertical waves and horizontal electromagnetic waves. Mr. Weagent conceived the idea of using the two-loop aerial as a tank or resonator for the static waves that produce the clicks and clicks, and then avail of these at a given instant to balance out by means of the practically similar waves picked up in a third aerial that would convey the receiving circuit proper in the manner to be described.

Fig. 26.—Weagent Three-Wire Aerial Static Eliminator System.

Messages may be successfully received from across the Atlantic Ocean, with apparatus, including the entire equipment, and miniature aerials, so comparatively diminutive that they may be placed on a lecture platform.

Comments on Trans-Atlantic Wireless Telegraphy.—The Great War interfered materially with the free use of wireless telegraphy and during the term of the war the governments of the various nations of the world exercised complete control of its operation over land and sea. The following remarks concerning the status of trans-Atlantic Wireless telegraphy are drawn from an article in the 'International Cable Register Supplement,' by E. B. Pillsbury.

Regular message traffic has been transmitted between Europe and America by Wireless telegraphy continuously for over eight years by means of a duplex circuit between Clifden, Ireland, and Glace Bay, Cape Breton, that is, messages between those points are transmitted in either direction simultaneously. The transmitting and receiving apparatus are not placed in one station but in separate stations a number of miles apart, connected by land lines,
which make it possible to localize the sending and receiving operators in the one room. The receiving instruments are coupled to two distinct aerials, one of which is used for receiving while the other, known as the balancing aerial, is so arranged that it is practically unaffected by the signals from the distant station from which it is expected to receive. The effect produced by the balancing aerial on the receiving apparatus by the adjacent transmitter is equal and opposite to that produced thereby through the receiving aerial which is tuned to the wavelength of the signals it is desired to receive. The latest type of the Marconi receiving apparatus greatly minimizes the atmospheric interference to which wireless transmission over long distance was particularly exposed in the early days. The signals arriving in Glace Bay from Glidden are as a rule easily read through any ordinary electric atmospheric disturbance. The strengthening of received signals has made possible the employment of recording instruments which not only give a permanent record of the received messages, but are also capable of operation at a much higher rate of speed than would be obtainable by an operator receiving by sound or sight. The method employed for this purpose is to insert into a gramophone the wireless telephone whereby the received dot and dash signals are impressed on the wax cylinder. These signals may then be recorded at maximum speed and afterward be removed to another gramophone that may be speeded down to the capacity of the receiving operator. A high rate of transmission of signals is attained by the use of a Wheatstone automatic transmitter (see TELEGRAPHY) using perforated paper tape.

While the war has interrupted the free use of wireless telegraphy and telephony it has at the same time made demands upon the engineers of this country and Europe in the direction of improvements in these arts that have no doubt produced practical results that would not otherwise have been forthcoming in years. This has been remarkably true with regard to the improvements in vacuum-tube apparatus and the results obtained thereby in the service of the United States Signal Corps. For this service alone the production of high quality standardized tubes has been at the rate of over 1,000,000 per annum. For interesting data on this subject consult a lecture given by Maj.-Gen. George O. Squier before the American Institute of Electrical Engineers, 10 Jan. 1919, on "Aeronautics in the United States from the Beginning of the War to the Present Time."

Marconi Wireless Telegraph Station at Belmar, N. J.—The building shown in the foreground is the operating-room of the station. It is over 82 feet in length. This station is intended to communicate with the high power station at Carnarvon, Wales. The mast shown are 300 feet in height and extend westward one mile from the shore. The room containing the receiving apparatus is over 80 feet long. The messages received and transmitted from this station are sent to and from the Marconi offices in New York, London, and Paris. Similarly, messages are received and transmitted to and from the Marconi office in London to the high power station at Carnarvon.

Proposed Pan-American Wireless Chain of Stations.—It has recently been announced that the longest wireless station in the world is to be constructed near Buenos Aires, South America. This will be one of a series of wireless stations designed to connect the United States with all the important countries of South America, including Argentina, Brazil, Uruguay, Chile, Peru and Ecuador. Mexico and Cuba are also to be placed in wireless communication with these countries. The South American wireless system will connect at New York with trans-Atlantic wireless to Great Britain, Scandinavia and Russia and at San Francisco with the Hawaiian Islands and thence with the Orient. In the United States the system will...
with the 25,000 stations of the Western ad lines.

rials of the proposed station at Buenol will be supported by self-sustaining corresponding the towers of the station at Arlington, Va., which are d in the accompanying illustration. details of this projected chain of wire will be found in The Wireless g of Telegraphy.—Proceedings of Institute of engineers; Bucher, E. [Samuel, Count, African ex- Baromberke, Eastern Transylvania, March 1916. He won a distinguished the roll of African explorers by his of 1886-89, during which Lake ferd in size of the great lakes of Africa, was for the first time sighted men. The existence of a great lake known area between the Victoria and Abyssinia had for some years been and after the route in this direction 1 opened up by Joseph Thomson's through Masaill, Count Teleki was to take advantage of this open road. only made his way to the lake, but to its northern extremity, bringing usable observations on the geography, and ethnology of the country traversed. various subsequent journeys in Africa East, but resulting in no further ical discovery.

2MACHUS, tɛməkəs, in the Ho- war cycle, a son of Ulysses (q.v.) hope. He was still in the cradle when he went to the Trojan War. When his 2d absent from home about 20 Telemachus was urged by Athena 1, to appear to him in disguise a, a friend of Ulysses, to go and seek is the place of his residence and the his long absence were then unknown, l the courts of Nestor and Menelaus to form. He afterward returned to here the suitors of his mother, Penel- conspired to murder him; but he heir treachery. His father had arrived and two days before him, and was then use of Eumaeus, a faithful servant. us is the hero of Fénélon's famous 'Les Aventures de Télémaque' from e word Mentor has been adopted erial use. See Télémaque.

3MACHUS, a Syrian monk, who, in of the Emperor Honorius, about 400 ed into the arena of the Coliseum and l to separate the gladiators. He lost the hands of the enraged populace, occurrence is said to have influenced to discontinue gladiatorial combats, did soon afterward.

Maque, a romance by Fénélon. e is in form a novel, and relates stories of Telemachus in search of his father, Ulysses. In its flowery poetic style, however, and in its division into 24 books, it suggests the epic poem rather than the modern novel. It is based upon the Odyssey of Homer, and uses the mythology and introduces many of the characters of that poem. Its intention was primarily didactic. It was one of several works that Fénélon wrote for the instruction of the young Duc de Bourgogne, grandson of Louis XIV, whose tutor he was (1663-65), by his experiences and observation during his wanderings, in various lands and among different peoples, aided especially by the wise comments and interpretations of Minerva, who accompa- nies him in the form of Mentor, the young Telemachus, future ruler of Ithaca, and through him the future ruler of France, received those lessons on the proper conduct of life and especially on the duties of a king and on sound principles of government, which were calculated to prepare them for the responsibilities of their high stations. It is a striking mark of the honesty and independence of Fénélon that these lessons are singularly liberal and modern, and contain implicitly some axioms of the government and policies of Louis XIV. 'Télémaque' has often been translated into English. Arthur G. Canfield.

TELEMETER, any one of various instruments designed to measure the distance of objects more or less remote. It is used by surveyors and engineers, wherever rapid work is necessary and a fair amount of accuracy required, on the battlefield to determine ranges, etc., where it is usually called a range-finder. One form is a recording apparatus electrically connected with a distant meteorological or other instrument. The surveyor's telemeter is better known as a stadia, and consists of a mounted telescope with horizontal cross-wires, which, when in use, intercept the divisions upon a graduated rod held by an assistant at the distant point. The reading multiplied by the factor of the instrument gives the distance.

TELECEPHALL, that is, (Gr. τέλεος) complete (Gr. κεφαλή) head. A name applied by some authorities to a group of fishes embracing most of the teleosts, or true fishes, especially those bearing a full complement of cranial and opercular bones, with the anterior vertebrae separate.

TELEOLOGY (Greek, telos, 'end' or 'purpose') denotes a mode of explanation in accordance with which the world as a whole, or particular forms within it, are regarded as due to the realization of some end or purpose on the part of some intelligence existing either in the world or outside it. Thus we might account for the various arrangements of the physical universe—the distribution of land and water, the movements of the heavenly bodies, the changes of the seasons—by referring them to some end that the governing power of the universe is thereby achieving, as, for example, the preservation and comfort of mankind. Or we might explain the structure of an organism or of any of its parts by reference to the purpose that it serves, as, for example, the presence of fish in the sea through their usefulness to man as food, or the structure of the eye through its service that it renders. It is natural to assume that everything has been made for man and to
regard all things as existing for his service and convenience, that "even the cork-trees," as Hegel remarked in satirizing this view, have been produced in order that we may have stoppers. The doctrine of teleology does not always adopt this narrowly anthropocentric point of view. But the very essence of its procedure is to postulate the existence of some intelligible ends or purposes in the world, and to read the various natural phenomena by reference to these ends. It is thus explained in terms of final causality, rather than in terms of efficient causes or mechanism. Teleology seeks to make things intelligible by showing their relation to an end that is being realized; it answers the question "Why?" or "For what purpose?" Mechanism, or explanation by efficient causes, on the other hand, knows nothing of a purpose. It shows how the result has actually been produced by the operation of natural causes, acting according to invariable laws. It explains by answering the question, "How?" It is well known that there has been a constant conflict, throughout the whole history of thought, between teleological and mechanical modes of explanation. Indeed, this may be said to be the supreme question at issue in all philosophy. Is the world and all that it contains merely a natural product of efficient causes acting without any intelligent guidance, or is there some purpose or system of purposes being realized?

The terms in which the conflict between teleology and mechanism are expressed have been modified in recent times, and it is perhaps well to note some fundamental differences between the thought of the present time and the earlier mode of conceiving teleology. The older teleology regarded God (or the gods) as a being outside of the world who in an external way was accomplishing some purpose through it, as the mechanic uses a machine to accomplish his purposes. From the modern point of view, God is identical with the ultimate principle of things. The purpose of the world, if any intelligible purpose exists, is not something superimposed on it from without, but an inner or immanent purpose to which it naturally and everywhere gives expression. The general ac

rather true that as mutually complementary conceptions they presuppose each other. Modern teleology admits to the full the rights of mechanical explanation in every field. But it insists that the fact of the existence of the world is a matter of our intelligence demand that we shall everywhere go beyond this standpoint and recognize an underlying system of purposes in the world-process. The two modes of explanation are thus on different planes, and opposition between them on this account is not the result of any clash of the faculties of our mind.

As Lotze says: "The true source of life is to be found in showing how absolutely universal is the end, and at the same time how completely the significance of the mission which mechanism has to fulfill in the structure of the universe.

Both a mechanical and a teleological view of the world was developed by Greek philosophers, the former by the Atomists, of whom Democritus is chief, the latter mainly by Plato and Aristotle. The Atomists united with the general spirit of the Christian doctrines, made the teleological the prevailing mode of explanation during the Middle Ages. The pioneers of modern thought, — Galileo, Bacon, Descartes, Gassendi, Hobbes, Spinoza, — worked out the mechanical theory, making it a powerful instrument of research by basing it on exact mathematical principles. They were strongly opposed to teleology, which they regarded as entirely unable to furnish scientific explanations of natural occurrences. Leibniz was perhaps the first thinker in modern times who saw that teleology and mechanism can be reconciled by properly distinguishing the planes where each principle has its valid application. For Kant (whose treatment of teleology is very important), mechanism is the only principle that we can confidently apply in science as objectively determining phenomena. Teleology, on the other hand, although a necessary subject for thought when we are dealing with organic phenomena, cannot be given a valid application. Living things must appear to us as if they were determined by some end, but we can never say that this purpose is actually present outside our minds in the objective phenomena themselves. At the same time, while mechanism is and must remain the sole principle of determination in the phenomenal world, Kant teaches that we are obliged to postulate a world of noumenal or more ultimate reality where teleology, by recognition of a moral purpose in the world, becomes the final determining principle. LEPATHY, the transfer of thought
one mind to another at a distance, es-
by the sending and receiving of definite
information from the mind of one
person to the mind of another person, beyond
reach of any of the five senses, without
mechanical aid. The sympathetic con-
mind of mind with mind is more or less ap-
plies to all, but whether this can be expanded
the full extent of the definition is doubted
by physicists, and regarded as not proven.

Within recent years, the study of
knowledge, spiritual mediumship, hypnot
mind-reading and thought transference
have led some eminent scientists to
it themselves definitely to accept with
such phenomena. It appears also that all
sages, yogis, theosophists, clairvoyants,
impy mediums, and seers believe in telep
and many of them have written volumes on
these subjects and those of which they
made record.

ere is seemingly no end to records of ex-
cesses of individuals which go to prove
thy, but these records, to be found in every
library, have no effect on the mind of the
sages who insist that he be shown — that
made apparent to one of his five senses that
thing exists. In the very nature of the
ought to be apparent that communica-
y means outside of the five senses cannot
ought and put upon a table and exhibited
benefit of people who want to see and
em. The evidence can come only from
people who have developed their powers
and thought to the extent of being able
t from a telepathic communication,
t send or receive one, or both.

Even a sender may have to depend much on
by the receiver, and the receiver on
racy of the sender, as they put together
periences, to obtain the proof of telep
ists. Those persons conclude that they
had telepathic communication, and tell
about it they are sure to be discredited
st of their acquaintances, who conclude
ese things are hallucinations. No physi
physical proof as yet can be adduced of
periences. If telepathy be a fact, and
on after death, it should be possible to
icate telepathically with the dead. And
just what spiritualists and many psychi
earches believe happens. It is a curious
that those who doubt communication with
ates intelligences, as by the Ouija board
ough a medium, are always claiming that
omena are probably produced by the
of some one who knows the facts of
ssages and influences the medium. Ob-
if mind can act on mind, telepathy is a
ad should furnish a bridge for communi-
between the world of the dead and the
And that is exactly what Sir Oliver
Camille Flammarion, Cesare Lombroso,
Doyle and other people of great intelli-
ave been trying to inform the public for
years. But because the evidence
cannot be handed out like a Sunday newspaper,
or put into a receipt so that anybody can tele-
path, the "material scientists" have largely re-
fused credence. Their attitude is changing,
however, and largely through the work of the
Psychical Research Society, which was started
with the idea (in many minds) of wholly dis-
proving spiritualistic phenomena, and has after
35 or 40 years convinced probably all of its active
members that the dead live on, and that more or
less communication is all the time taking place
between the two worlds. It was under their
auspices, a few years ago, that Prof. Henry
Sedgwick investigated 17,000 cases of appar-
tions of dead persons seen and recognized by
friends at a distance at the time of decease.
He reported that the result showed "coin-
cidences" 440 times as numerous as they should
have been under the law of chance.

Thought is a power, as is seen when great
orators sway audiences, or as history discloses to
us through the progress of an idea; hence it
is logical that thought should be able
to manifest itself at a distance, as do the
vibrations in radiography. For success in telep-
athy two minds in rapport are required, or
as the radiographer would say, the two minds
and it seems that these minds usually must belong
to egos sufficiently advanced that they know
they possess minds that they can control, and
who have practised this control until they can
concentrate on a given thing for a period of
many minutes, in some cases hours. Having
acquired this power of concentration, the telep-
ather must then send a definite sharply de-
defined thought to a receptive individual, or one
who is in known harmony, and preferably who
has arranged to have his mind receptive at
a given time. The message sent should consist
of concrete ideas rather than specifically formed
sentences in words. Probably meaningless
bers are the hardest things to convey telepathi-
cally, and yet members of the Psychical Re-
search Society met with considerable success
in sending numbers, and a lady of the writer's
acquaintance found the combination of a safe
and opened it, though previously she knew so
little about safes that she did not think that
the knob was to be turned alternately to the
right and left. Consult 'Proceedings of the
Society for Psychical Research'; Besant,
A., 'Thought Power' (1900); Rider, F., 'Are
the Dead Alive?' (New York 1909). See
Hypnotism; Psychical Research.

CHARLES H. COCHRANE.

TELEPHONE, The. Introductory.—The
word "telephone," derived from the Greek,
means "a voice from afar." Although the word
has sometimes been applied to non-electrical
devices for conveying sound by vibra-
tions, transmitted through tightly stretched
strings or wires by means of diaphragms con-
ected thereto, the term has now generally come
to mean the electric speaking telephone. In
all electrical telephone systems the acoustic
waves of condensation and rarefaction, set up
in the air by the speaker's voice, are directed
against the diaphragm of a transmitting instru-
ment. This transmitter converts these acoustic
waves into electrical waves of the same fre-
quency and shape. The latter travel as an elec-
tric current of varying strength over the tele-
phone line to the receiving instrument. In the
receiver the electrical waves pass through a coil on a magnet. The varying field of magnetic force which they produce causes motion of the iron diaphragm of the receiver, acting as the armature of the magnet. The motion of the receiver diaphragm sets up acoustic waves in the air, similar in frequency and form to the waves produced in the air at the sending end by the voice of the speaker. These acoustic waves, impinging upon the ear of the person at the receiving end of the line, reproduce the words of the speaker. (Fig. 1).

Invention of the Telephone by Professor Bell.—Not only is the use of the telephone greater in America than in any other portion of the world, but telephony is notably an American art. The telephone was invented in America by Alexander Graham Bell and substantially all of the important contributions to the development of the telephone art have been made by Americans. Professor Bell was a teacher, at Boston University, of a system of visible speech for deaf mutes, devised by his father, who had studied the science of acoustics. Father and son had made together numerous researches into the relations which existed between the different elements of speech, and the musical relations of the vowels. Professor Bell was a close student of the researches of Helmholtz, and his studies of the latter’s experiments concerning the artificial reproduction of vowel sounds by means of electric tuning forks led him into the study of the application of electricity to acoustic instruments. While teaching at Boston University, Professor Bell occupied his spare time in efforts to realize his dream of the telephone, and also in experimenting upon a system of harmonic telegraphy designed to send several differently tuned, and therefore, non-conflicting telegraph messages, over a single wire at one time. While experimenting on the harmonic telegraph, Professor Bell had before him continually a vision of transmitting speech electrically. In the summer of 1874 he made a sketch of his conception of a speaking telephone which, although not tried that at time, became a part of, and was shown in, his first patent of 7 March 1876. (Fig. 2).

His conception was that the vibrations of the air produced by the voice speaking into mouthpiece A would cause membrane D, connected to steel reed C, to vibrate, thus inducing an undulating electric current to flow from coil B, over line E, through coil F at the receiving end to ground. This would cause the steel reed at the receiving end to vibrate and to transmit its vibrations to the receiving membrane I, causing the latter to produce air waves corresponding exactly to those formed by the voice at the sending end.

On 2 June 1875, while experimenting with harmonic telegraph, a demonstration of a principle on which he had based his speaking telephone of 1874 was successfully performed for him. In tuning the harmonics (Fig. 3) it was Professor Bell’s habit to snap the reed closely to his ear to determine the frequency of the tuning. While doing this he startled to hear the twang of the vibrating steel spring. Going quickly to the semi instruments in an adjoining room, he found his assistant, Mr. Thos. A. Watson, had one of the springs in order to free it from its spring that Professor Bell had him snapped spring having generated an alternating current in the coils of the semi instruments in which traversing the line and passing through the reed caused the sound to be reproduced. (Fig. 4.)
Fig. 11 — Box Telephone. Cover Removed. Made in June, 1877. Equipped with a sheet iron Diaphragm and the Watson Hammer Signal or "Thumper." First form of telephone equipped with a signalling or calling device. This instrument was used interchangeably as transmitter and receiver.

I do the same for any sound, even that of my own voice. On the next day he gave instructions for the making of his first real telephone, known as the Galloway type, (Fig. 4). It consisted of a frame of wood carrying an electromagnet with a copper coil and an iron armature, the free end of which was fixed to the centre of a small drum head of the type used in telegraphy. A mouthpiece was provided for speaking purposes. With this instrument, the sounds were transmitted over a short distance and heard by means of a second instrument at the other end.

Professor Bell was then experimenting with his liquid transmitter, (Fig. 5). This instrument consisted essentially of a diaphragm, at one end of which was attached a small condenser, and at the other a liquid, which was able to be vibrated by the voice, to the sound of which a receiver was provided. The liquid was contained in a small cup, and the diaphragm was held by a small spring. The transmitter was connected in series with a battery and a tuned condenser receiver, (Fig. 6). Undulating waves were produced by the change in resistance of the circuit as more or less of the liquid was immersed due to the vibration of the diaphragm. With these instruments, Professor Bell speaking, and Mr. Watson listening, the first complete articulate telephone message was transmitted.

On 9 Oct. 1876 the first reciprocal conversation took place over an outdoor wire, two miles long, between Boston and Cambridgeport, Mass. The instruments (Fig. 7) had, as diaphragms, thin iron discs which responded to the voice vibrations. Close to, but not touching, the centre of the diaphragm was the core of an electromagnet, the windings of which were connected in series with a battery, the line and a similar instrument at the other end. With these instruments was carried on a sustained conversation which was fully reported in the next morning’s papers as the latest startling scientific achievement.

Professor Bell exhibited his telephone inventions at the Centennial Exposition in Philadelphia in 1876. There he demonstrated, before the judges of the exposition and a large number of people, the mechanical action of his open circuit instruments.
of people, his liquid transmitter (Fig. 5); iron box receiver (Fig. 8); single pole membrane telephone (Fig. 9), and other types of instruments. As a result of this exhibition of the telephone its fame spread rapidly.

Work of Early Investigators Preceding Bell.—The idea of applying electricity for the transmission of sound arose as soon as the effects of electric telegraphy were observed. Page, in 1837, discovered that a magnetic bar could emit sounds when rapidly magnetized and demagnetized. Electric vibrators devised by Macaulay, Wagner and Neef and adapted to produce musical sounds by Froment and Petrini in 1847 to 1852, showed that the transmission of sound to a distance was not impossible. Bourseul, in 1854, suggested that if one spoke near a movable disc sufficiently flexible to lose none of the vibrations of the voice, this disc, by alternately making and breaking the current from a battery, might cause another disc, at a distance, to execute the same vibrations simultaneously. Reis, in 1870, invented a musical telephone that, by alternately making and breaking an electric circuit, could transmit musical tones over a wire to a distant point. Reis' work, although urged as an anticipation of Bell, never found favor in the courts during the extensive patent litigation that followed Bell's invention because his scheme was based on making and breaking a current, which cannot transmit speech. The United States Supreme Court said "to follow Reis is to fail, but to follow Bell is to succeed." The publication of Professor Bell's invention brought forth many claimants to priority. After years of litigation in which the state of the art and the claims of others were considered exhaustively, priority for the invention of the telephone was finally awarded to Professor Bell. While Professor Bell, by means of lectures on the telephone, was arousing public interest in his invention, development work was begun to make the instruments more practical for general use. The box type (Figs. 10 and 11), which was the best form thus far devised, was not adapted to be held in the hand. The inconvenience of the box telephone led to the development of a style of instrument which could be held in the hand readily and used for transmitting or receiving as desired.

The Receiver.—Several forms of receiver (hand telephone) employing wood for the containing case were produced and placed in public use in the early days. Fig. 12 illustrates one of these. This type was subsequently improved in design and hard rubber replaced wood for the handle and ear-piece. (Fig. 13). Thus far the receiver had one pole-piece and coil placed on the end of a permanent magnet. In 1890 the first type of receiver having two pole-pieces and coils was developed. The bi-polar receiver has passed through a long period of evolution, each successive step in the development increasing its talking efficiency or improving the mechanical features of its design. Fig. 14 shows the bi-polar receiver in use at the present time in the Bell System. Two permanent magnets are used. To their poles are welded soft iron pole-pieces which constitute the cores of the electro-magnetic coils. The supportin of non-materi welded magnetic cores, thinning a rig which is ed within rubber, ca ear cap-

card diaphragm ly in plac e, but not ing, the pieces. Each is carefully edmate manufactured extremely rate dime and the w assembled tested with utmost order the s instruments greatest able eff and mec strength is secured over 50 di types and for use in the Bell System. Practically these have been abandoned in favor latest improved type. While great in terms have been made in the design efficency of the telephone receiver, its mental electrical principle is the same as who invented it.

Out of Bell's several of useful transmitters coming of on the hand type of mitter. Several type receivers were growing in the principle differing what in of constant are uses. The hand mitter was sha develop into the magneto box transmitter 15). Except for very short lines, this type of transmitter was not sufficiently ful. The solution of the vitally impor-

Fig. 13.—Cross-section of improved Hand Telephone, with hard rubber of receiver handle and ear-piece.

Fig. 16.—Early form of Berliner Transmitter.
Emile Berliner invented a transmitter (Fig. 16) having, in contact, two pieces of carbon, the other capable of being moved by the voice. The principle was that two bodies in contact and forming an electric circuit, if the pressure on one was increased, the electrical resistance of the circuit is diminished and more current flows. Hence, the diaphragm of the voice, which is a metallic diaphragm capable of being vibrated by the voice. This diaphragm is in contact with a metal ball, and the metallic contact is at a. Vibration of the diaphragm, as explained above, causes corresponding changes in the current flowing in a circuit including the contact, a battery, the line, and the receiving instrument. In later forms of transmitters, carbon contacts were used instead of metal.

Edison invented a transmitter (Fig. 17) in which the current varies with the motion of a varying element containing a small disc of carbon (lamp black) between two electrodes arranged so that the current varies with the resistance of the carbon. In 1878, Francis developed an improvement in the Edison transmitter. He employed a platinum point against a hard carbon surface. Fig. 18 shows a section of a Blake transmitter. The platinum point is forced against the diaphragm by a spring. The voice is applied to the diaphragm, causing it to vibrate. The platinum point is forced against the diaphragm, and the voice is transmitted through the air.

In 1880, an English clergyman, Henry Hunnings, invented a transmitter employing granular carbon to secure a large number of points of microphonic contact. The essential feature was a thin platinum diaphragm in contact with a mass of granular carbon enclosed within a chamber having at the rear a plate of metal or carbon in contact with the granular carbon. In 1885, Bell engineers improved the Hunnings transmitter (Fig. 20) by using a horizontal platinum diaphragm and a gold-plated electrode dipping into the granular carbon. While this transmitter operated well when at its best, after being used for some time the large quantity of granular carbon produced an insensitive condition that seriously affected its efficiency.

To overcome this, A. C. White, in 1890, working in the Bell laboratories, invented the solid back transmitter (Fig. 21) in which the contact element is in the form of a small chamber (termed the "button") containing two carbon discs electrodes; one fixed, the other free to vibrate. These electrodes are separated by a small space partially filled with granular carbon. The fixed electrode is rigidly supported by the solid backing afforded by a stout metal bridge. The movable electrode is firmly attached to the centre of the diaphragm. The function of the granular carbon is the same as in the Hunnings type but the defects of the latter are overcome. This instrument has proved so perfect in its operation and so satisfactory in its general design that it has formed the basis of all the best types of transmitters.

A number of modifications from the original design have, however, been made to improve its electrical and mechanical features. Fig. 22 shows the construction of the "button" of the modern common-battery solid back transmitter. Over 70 different types and styles of transmitters have been developed and placed in service by the Bell system. Practically all of them have been displaced by the type just described. Transmitters employed by independent companies operate on the same general principle as the type just described.
described and resemble it in appearance.
